Work done at Facebook Novi

Byzantine Fault Tolerance

How to build (really) high performance blockchains

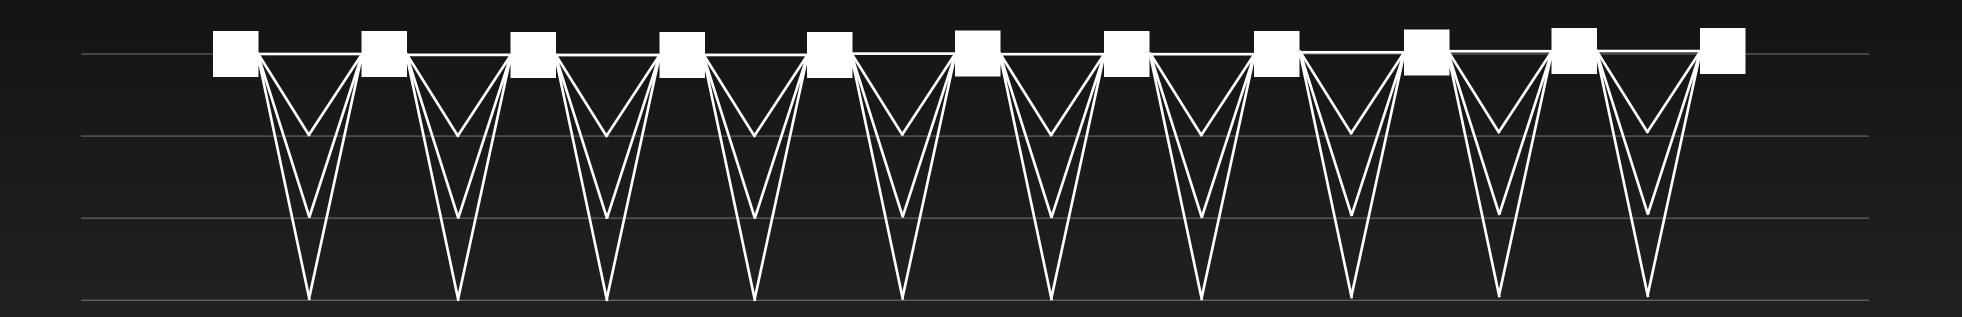

The goal of this project

Current Designs

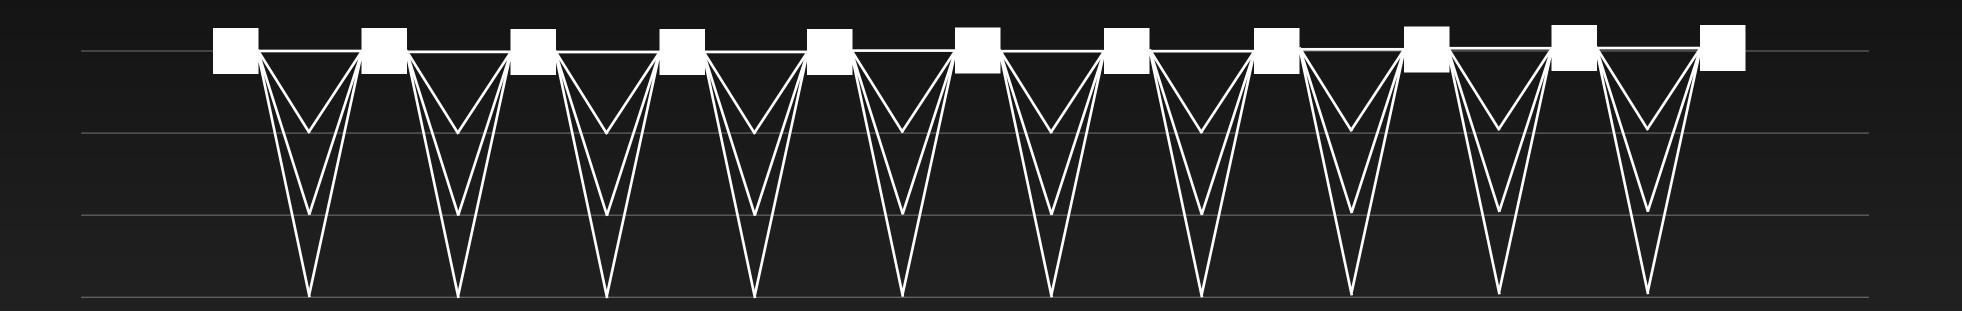

- Optimize overall message complexity of the consensus protocol

Monolithic protocol sharing transaction data as part of the consensus

Current Designs Typical leader-based protocols

Current Designs Typical leader-based protocols

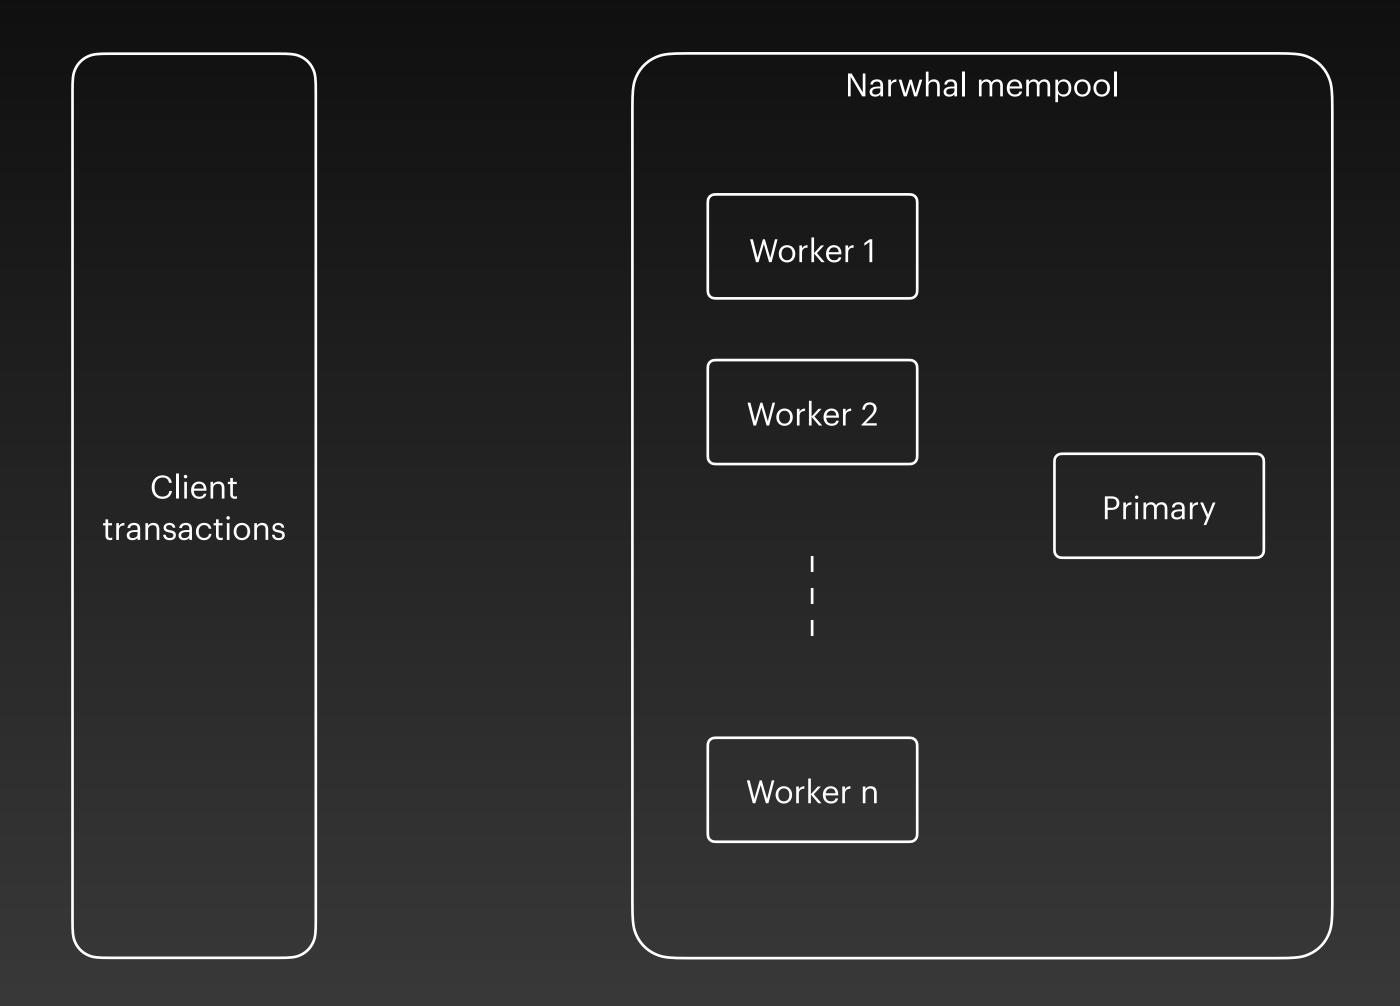

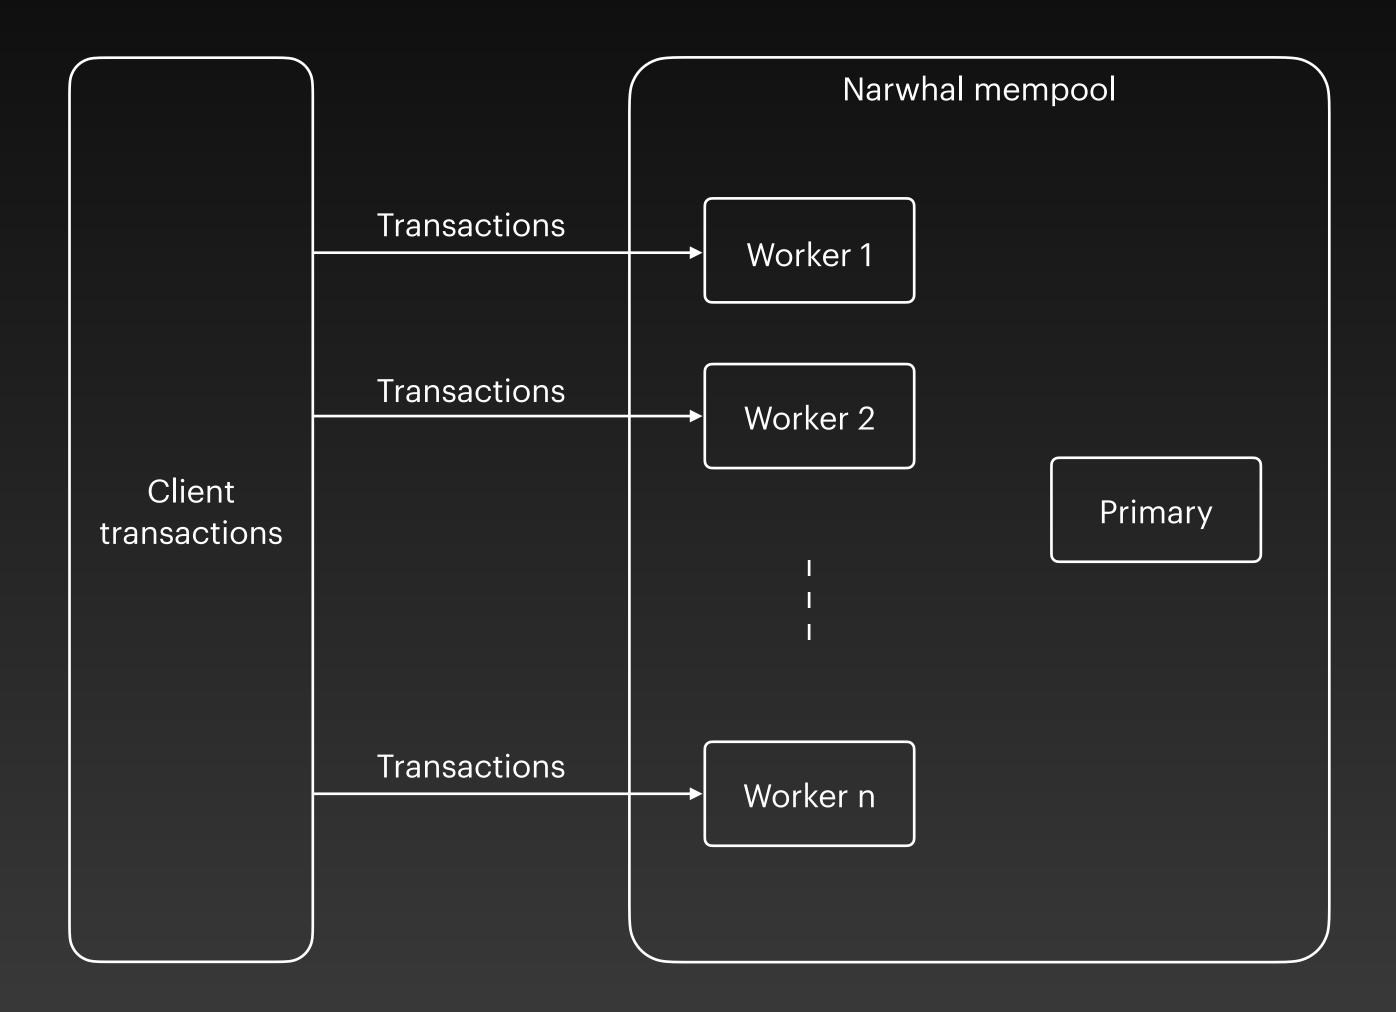

The mempool is the key

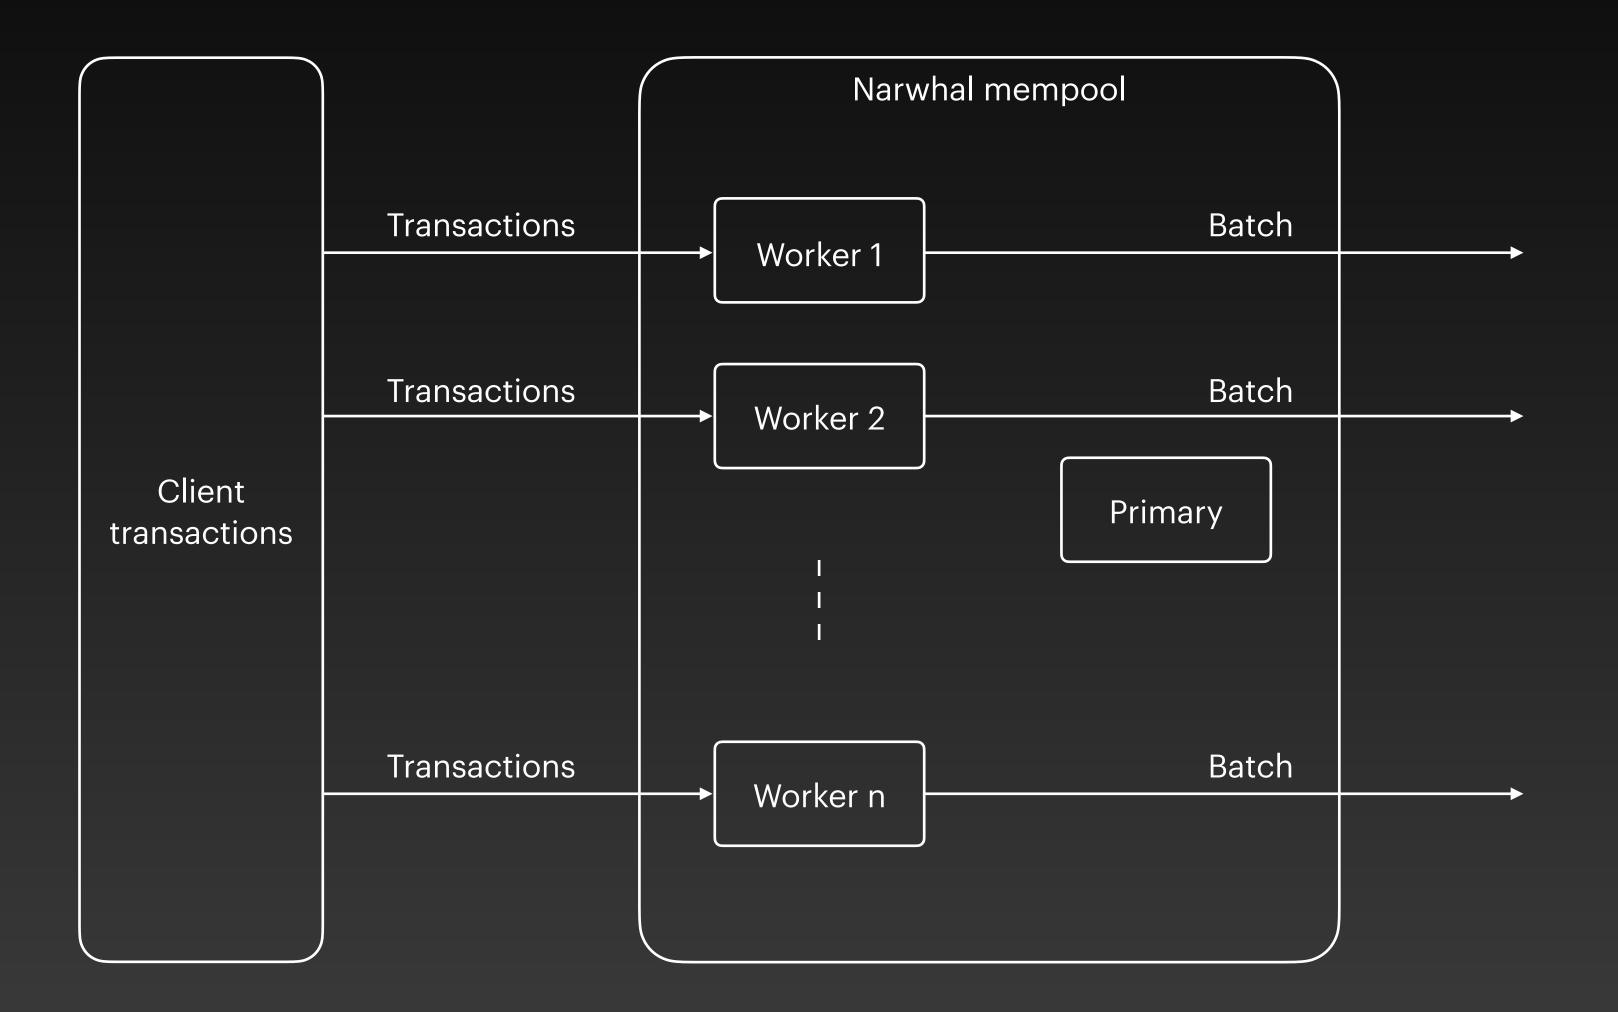

Reaching consensus on metadata is cheap

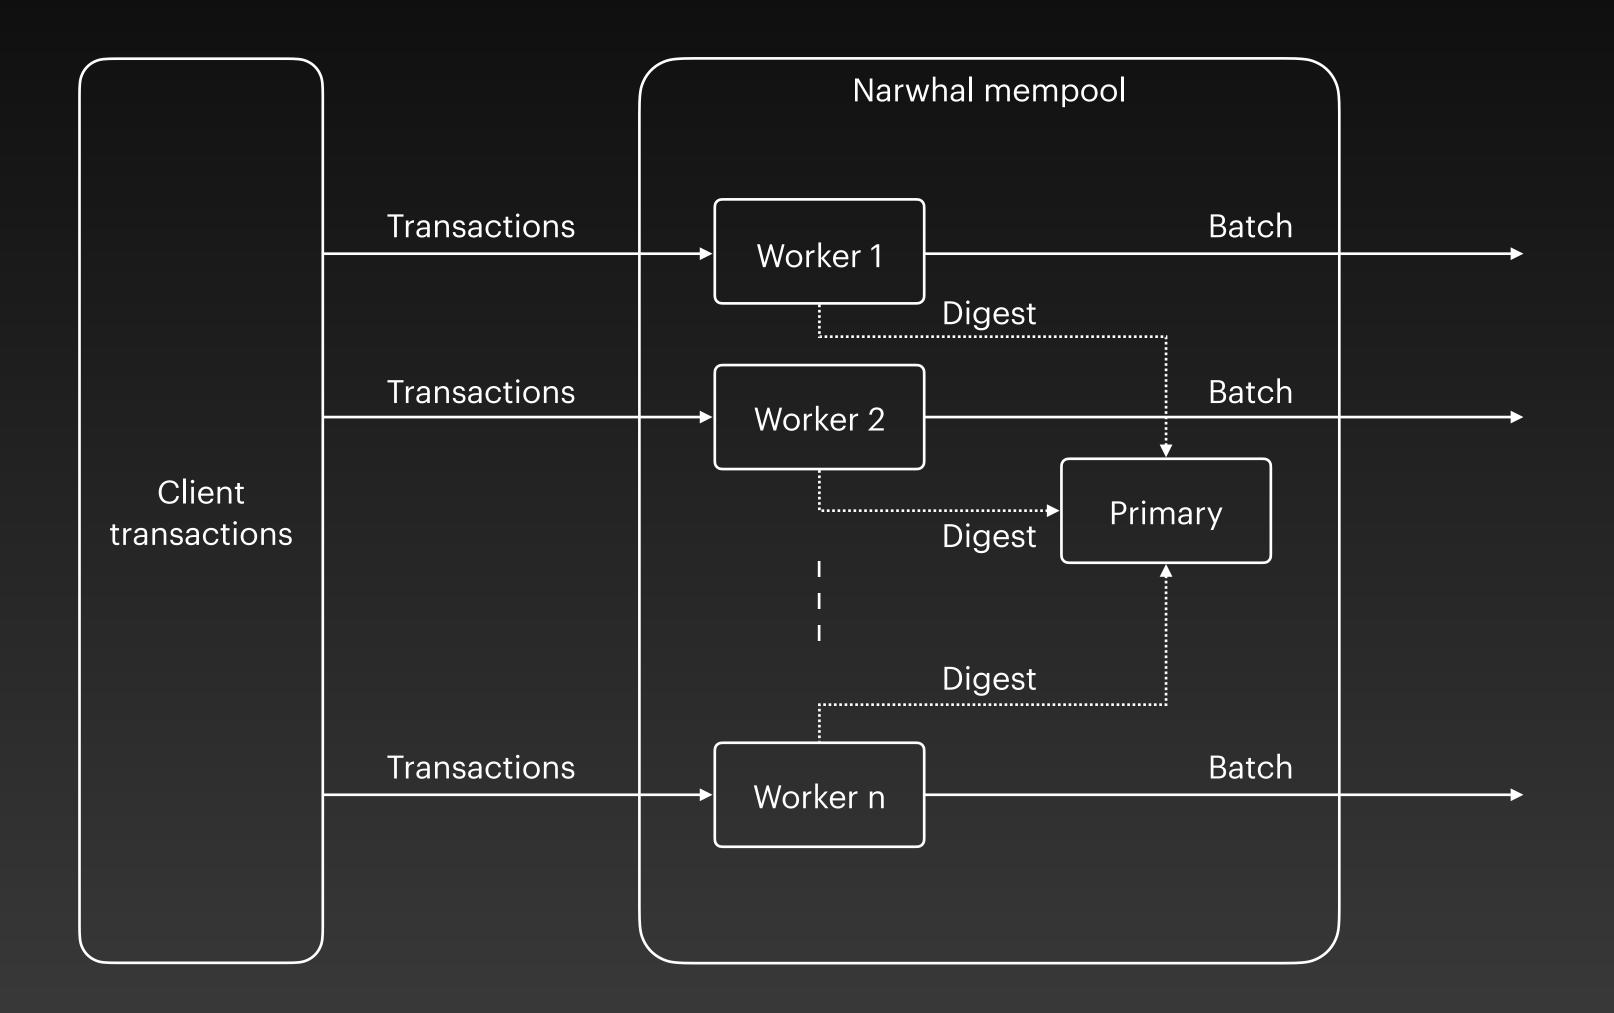

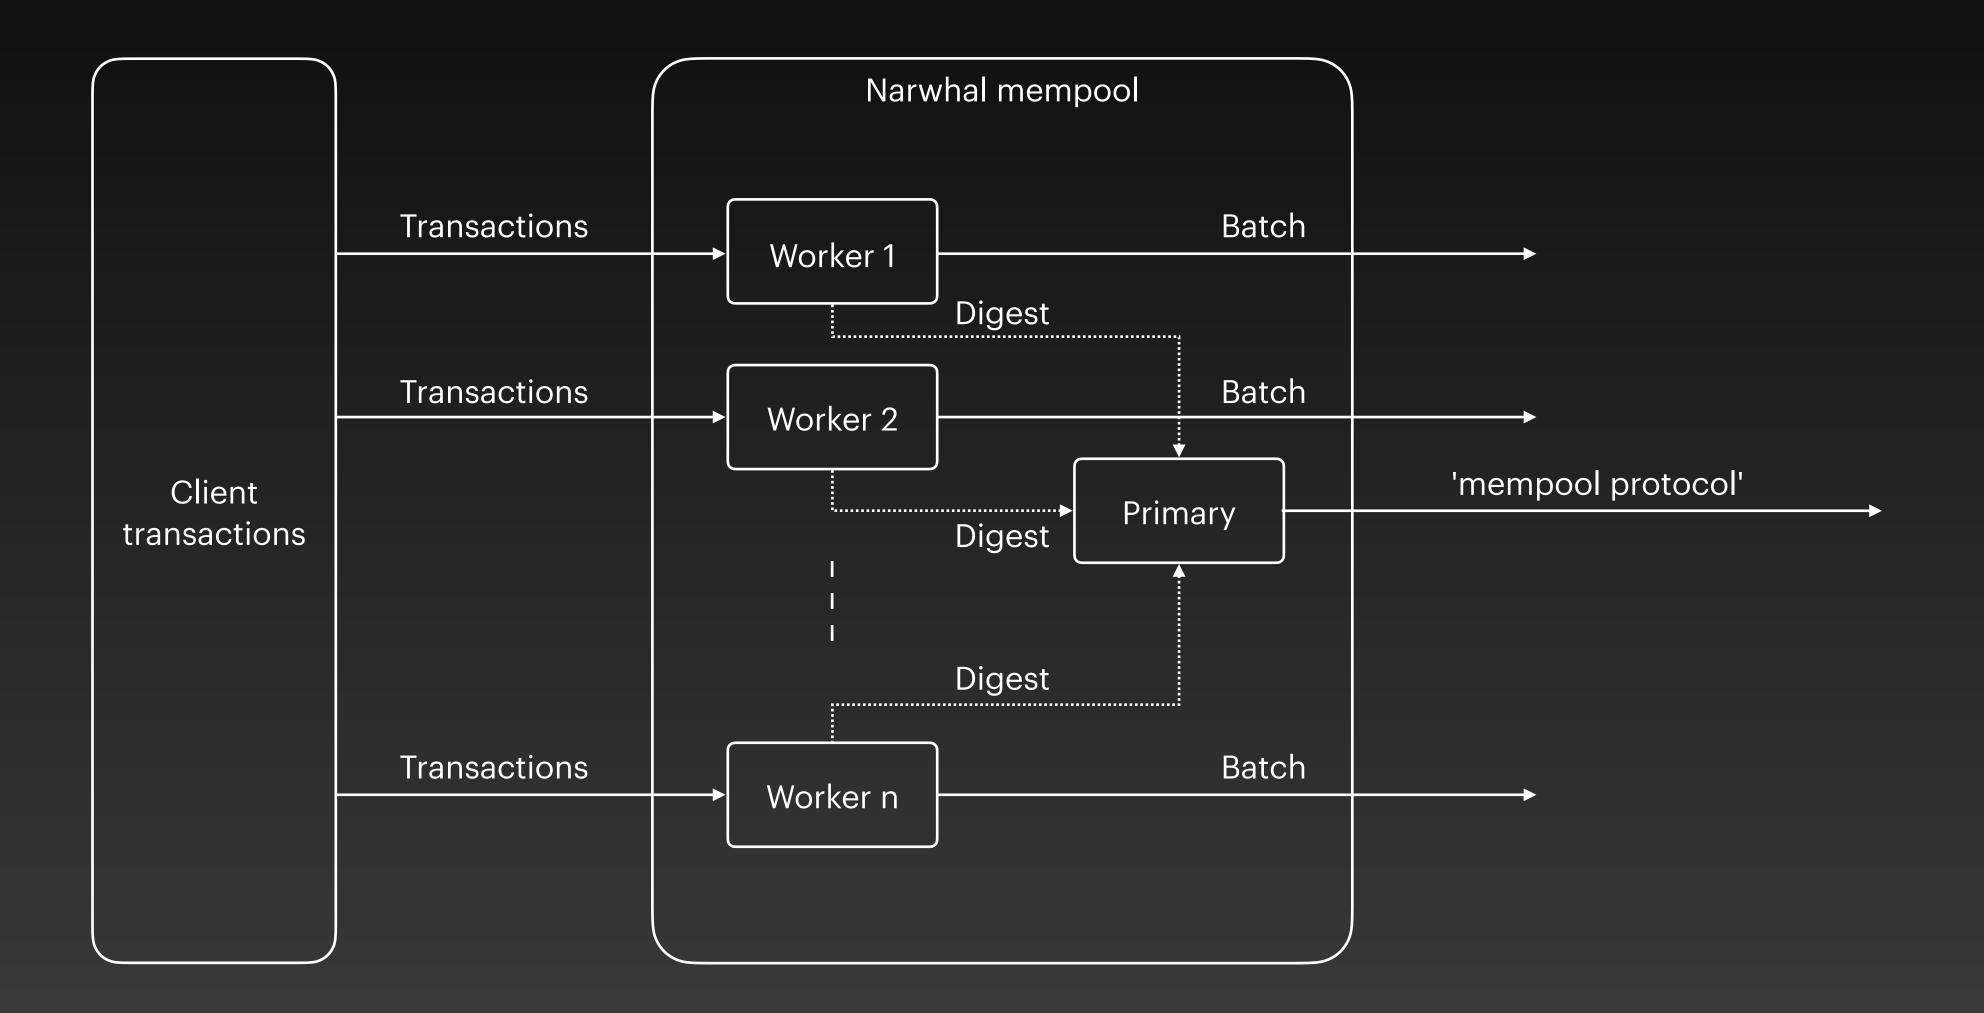

Dag-based mempool

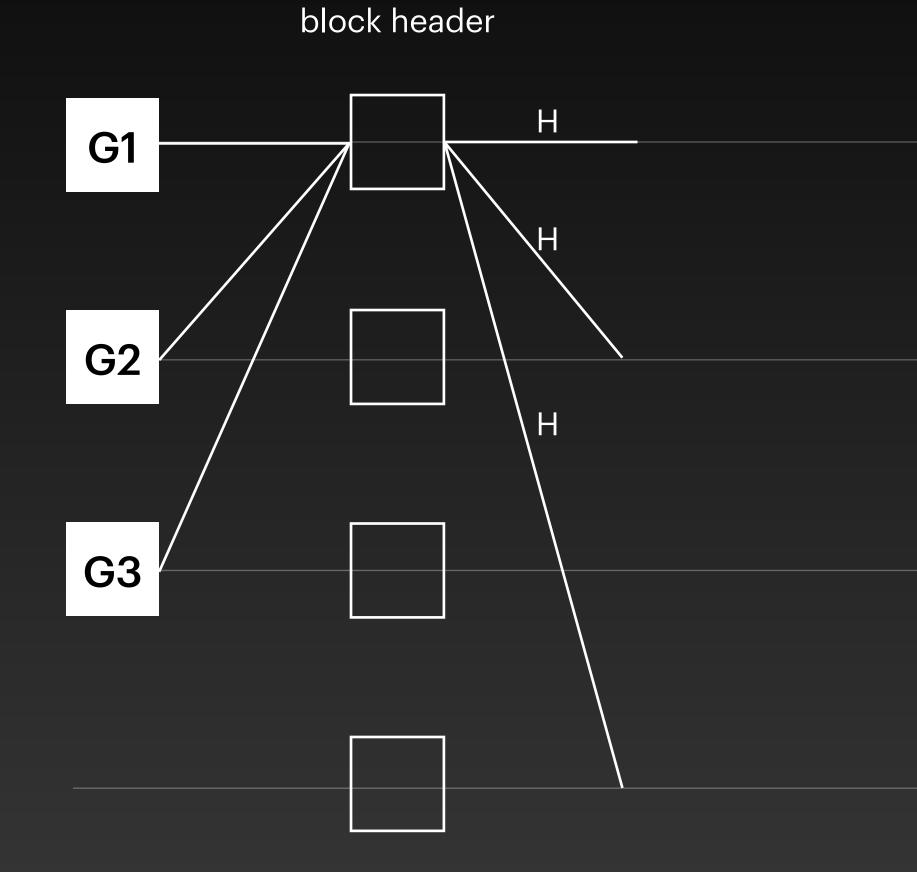

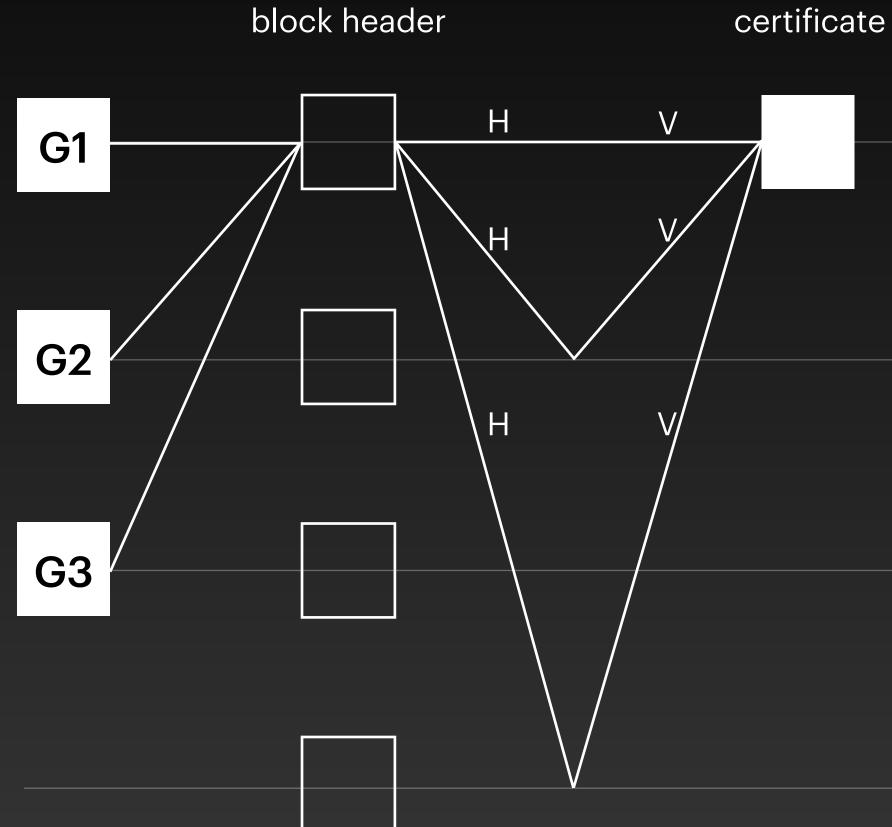

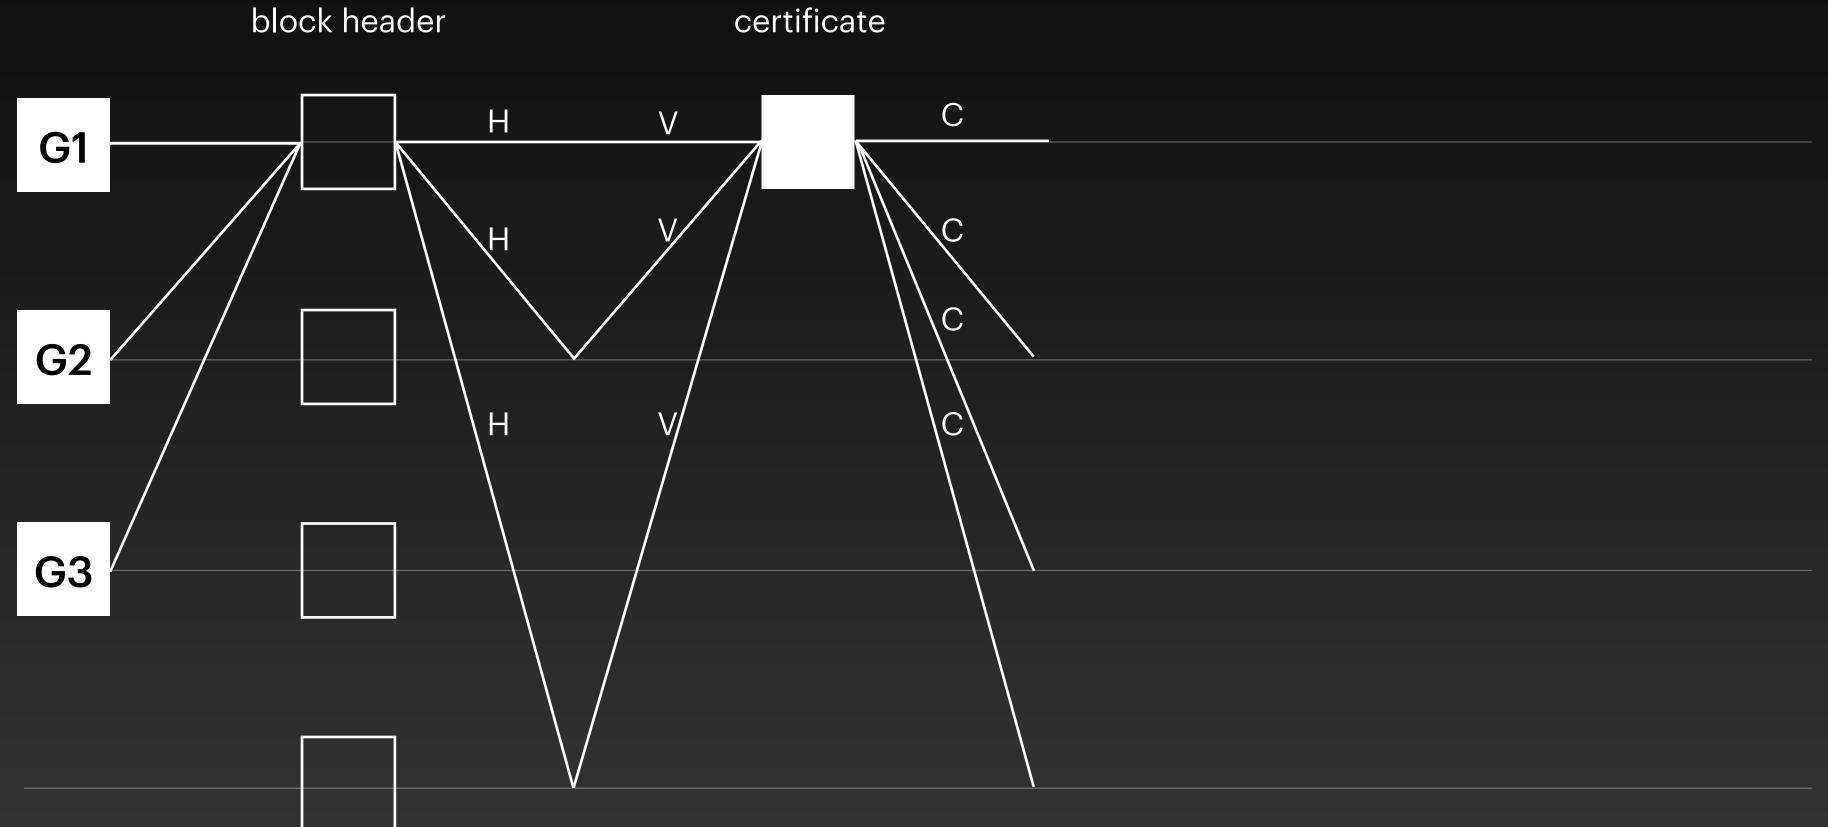

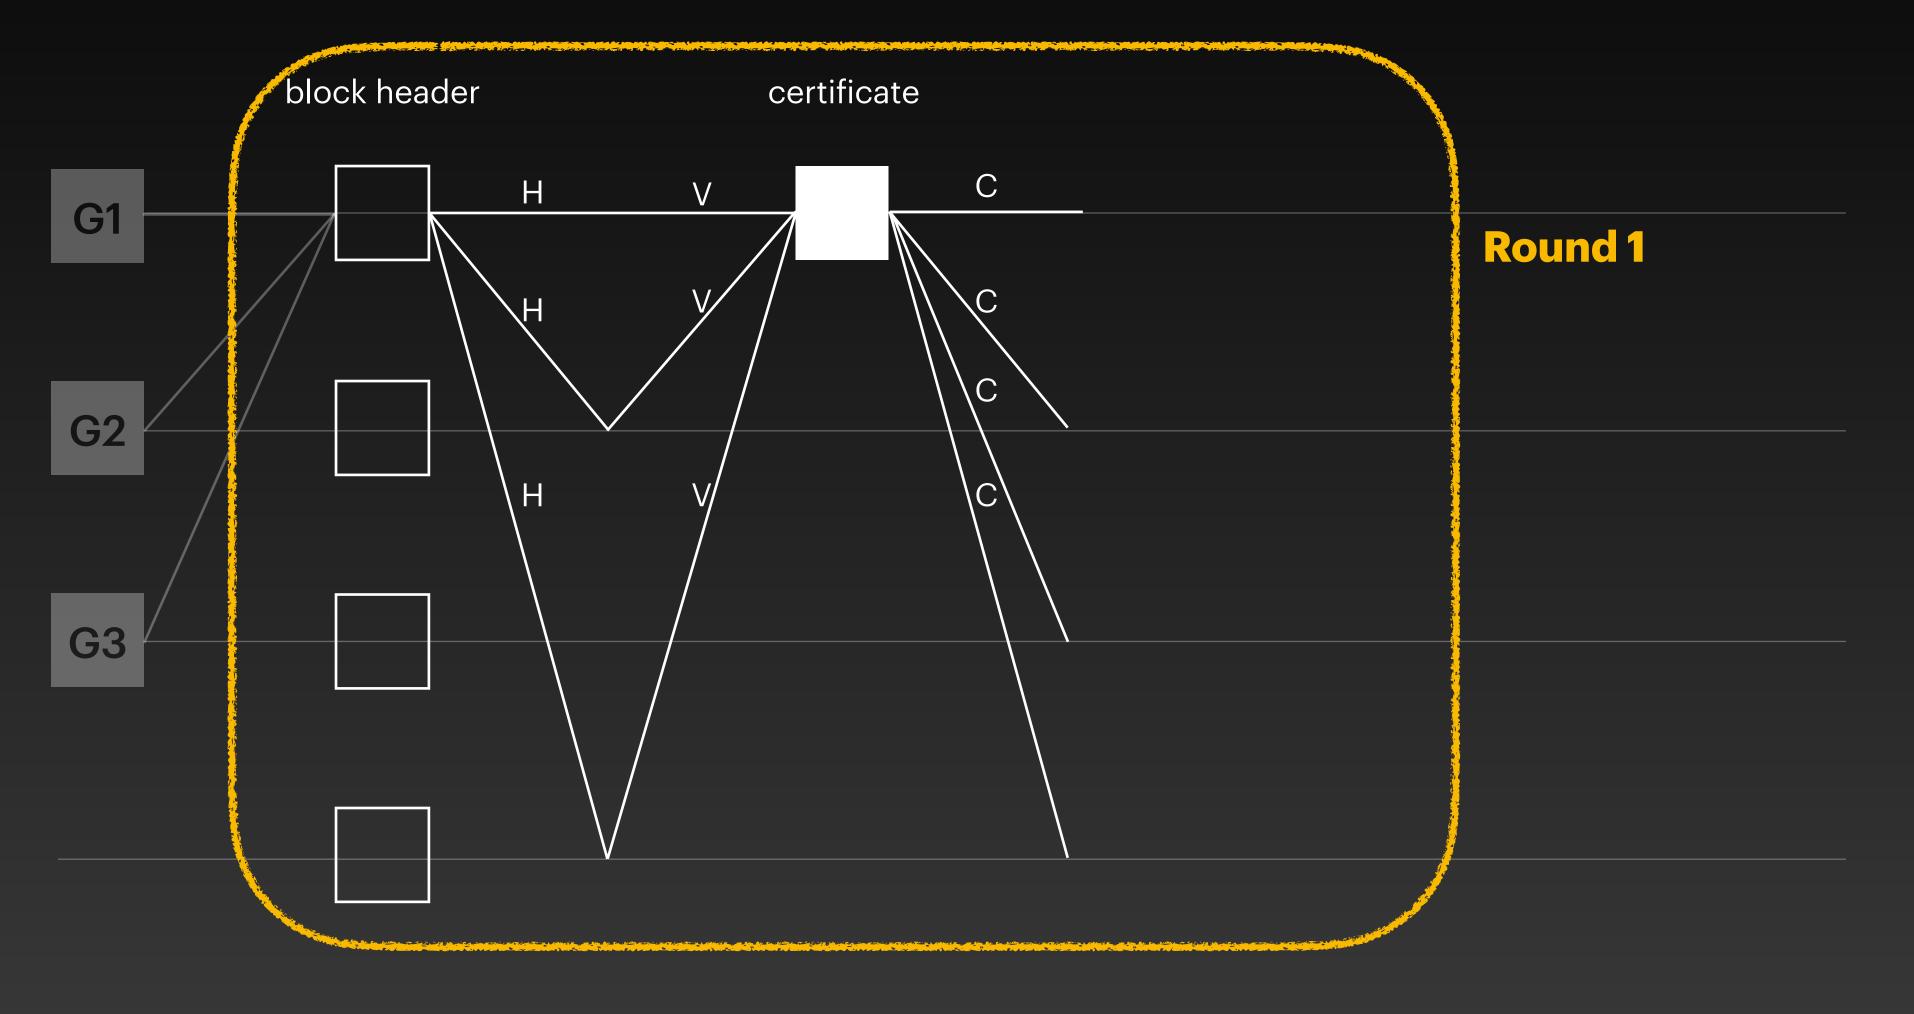

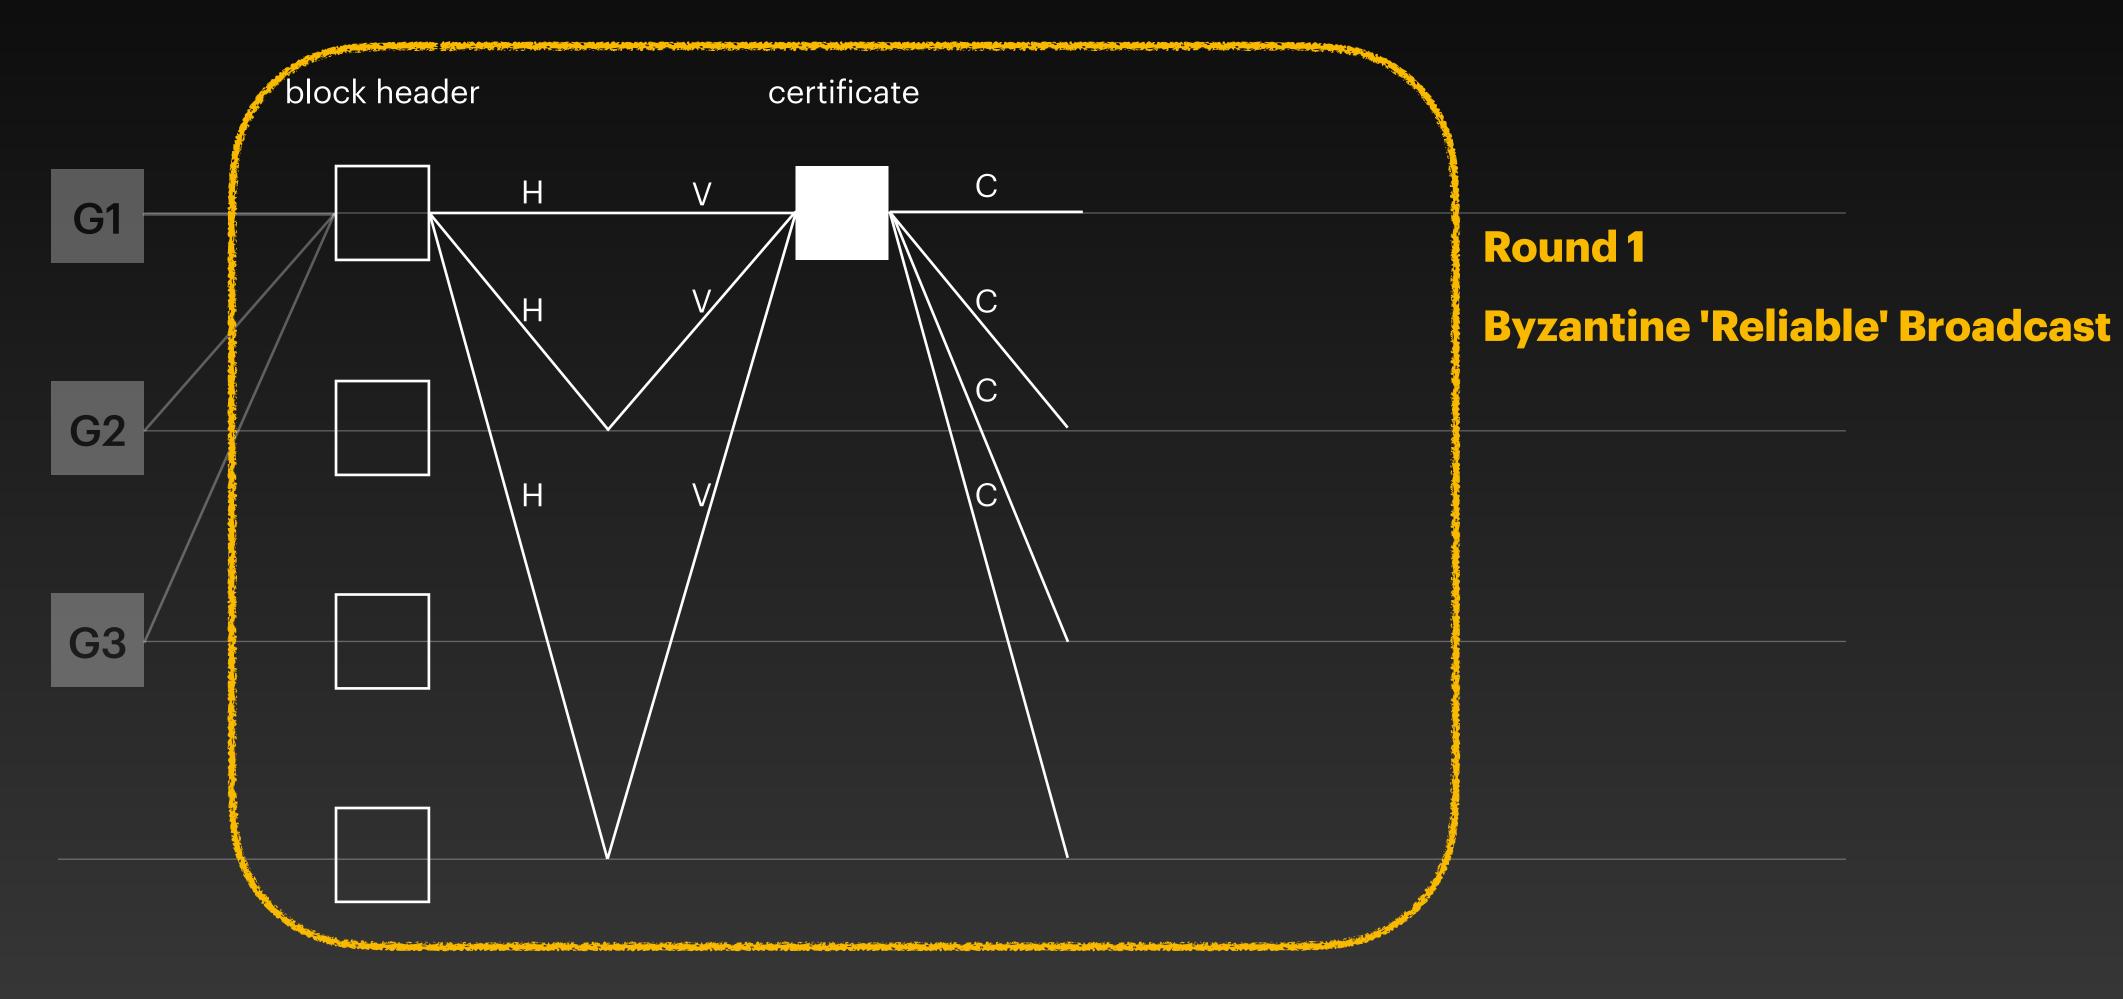

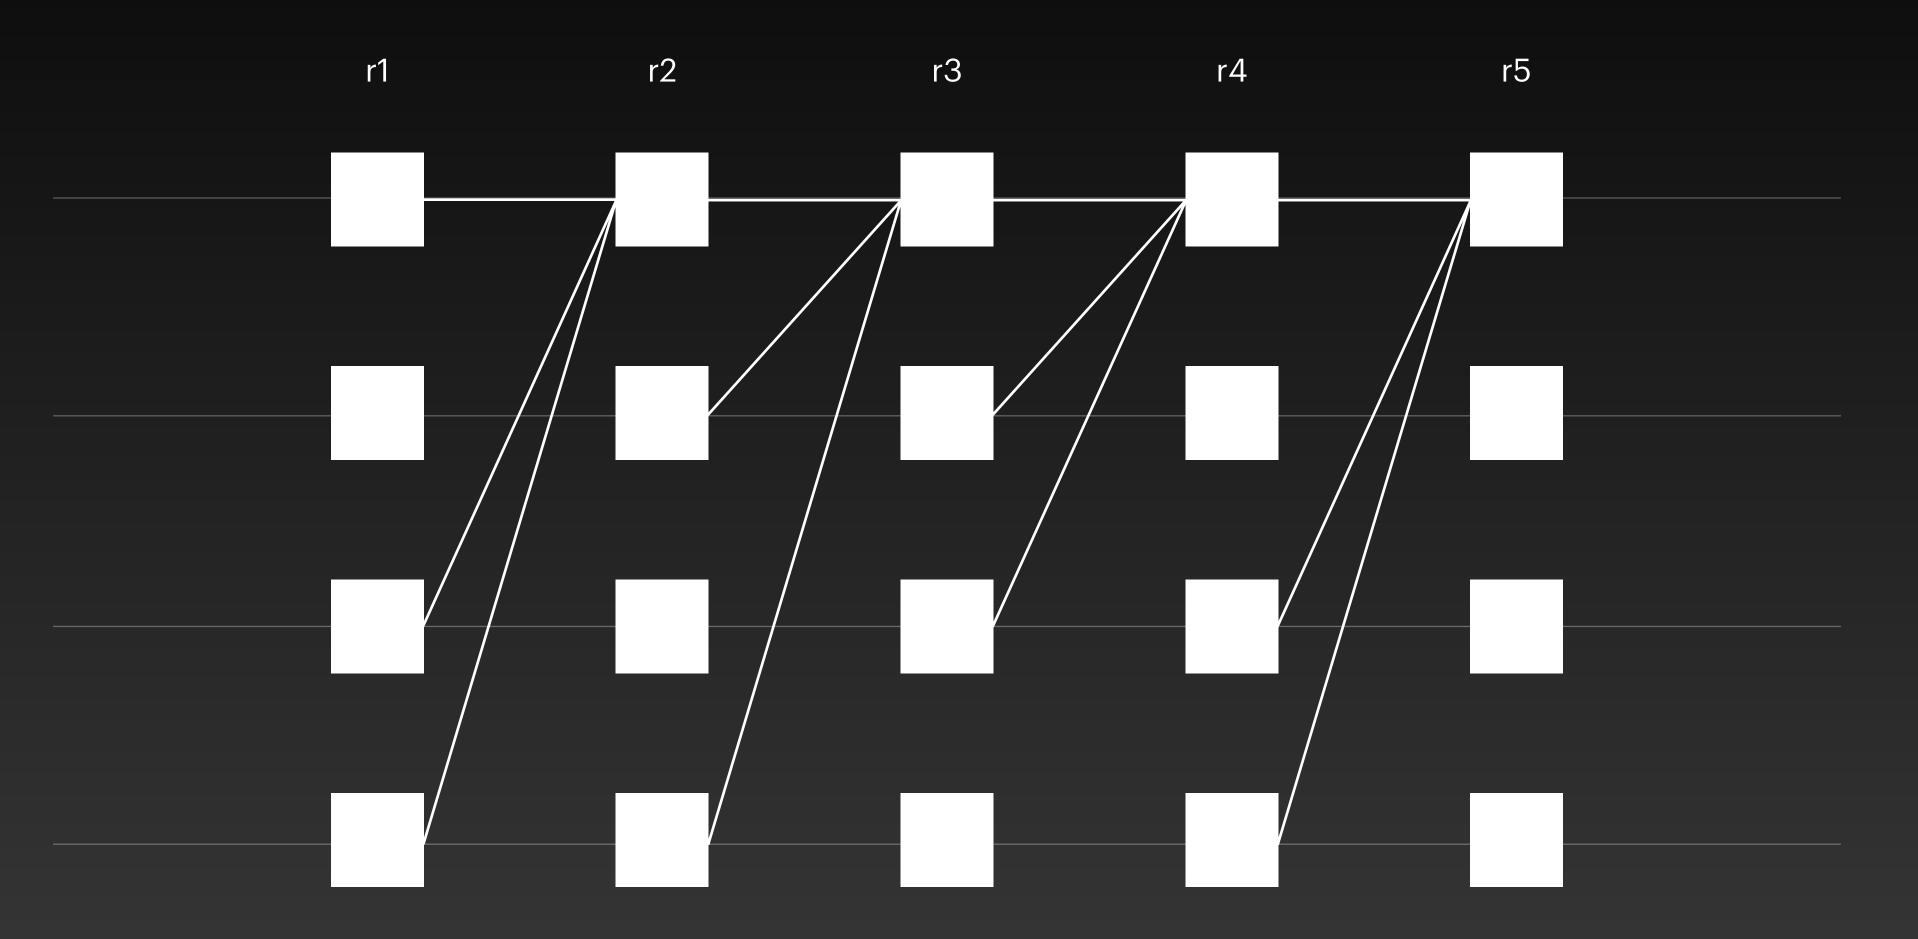

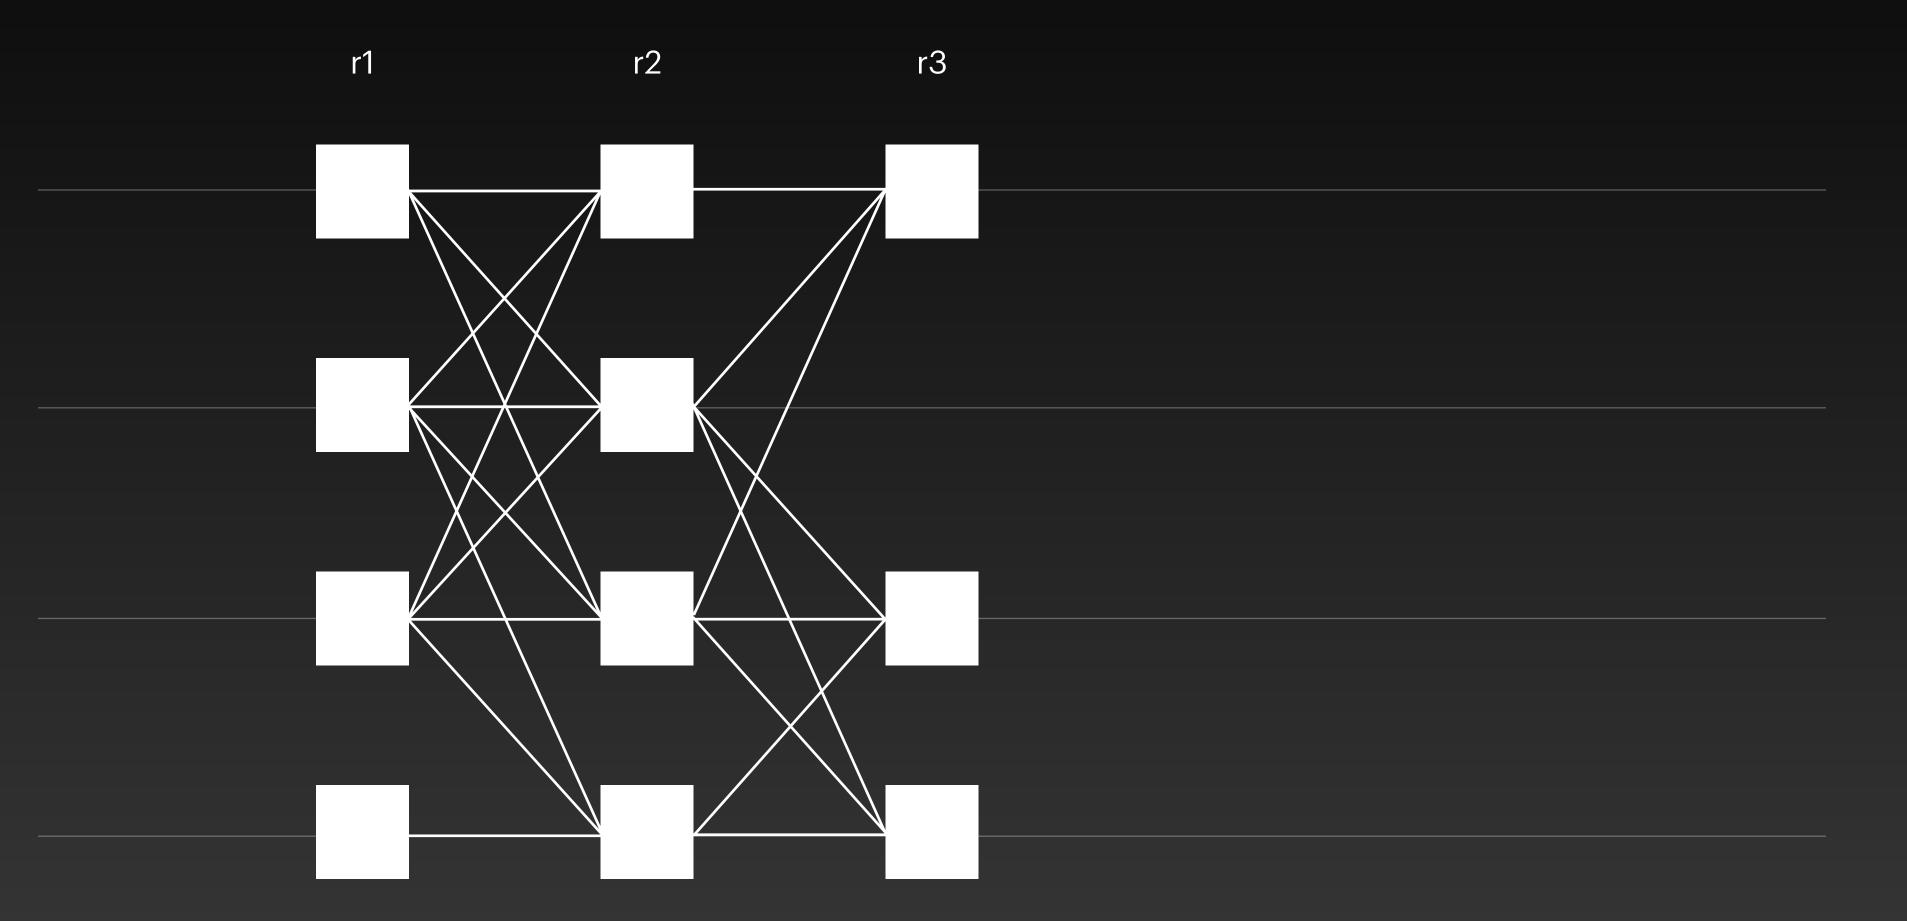

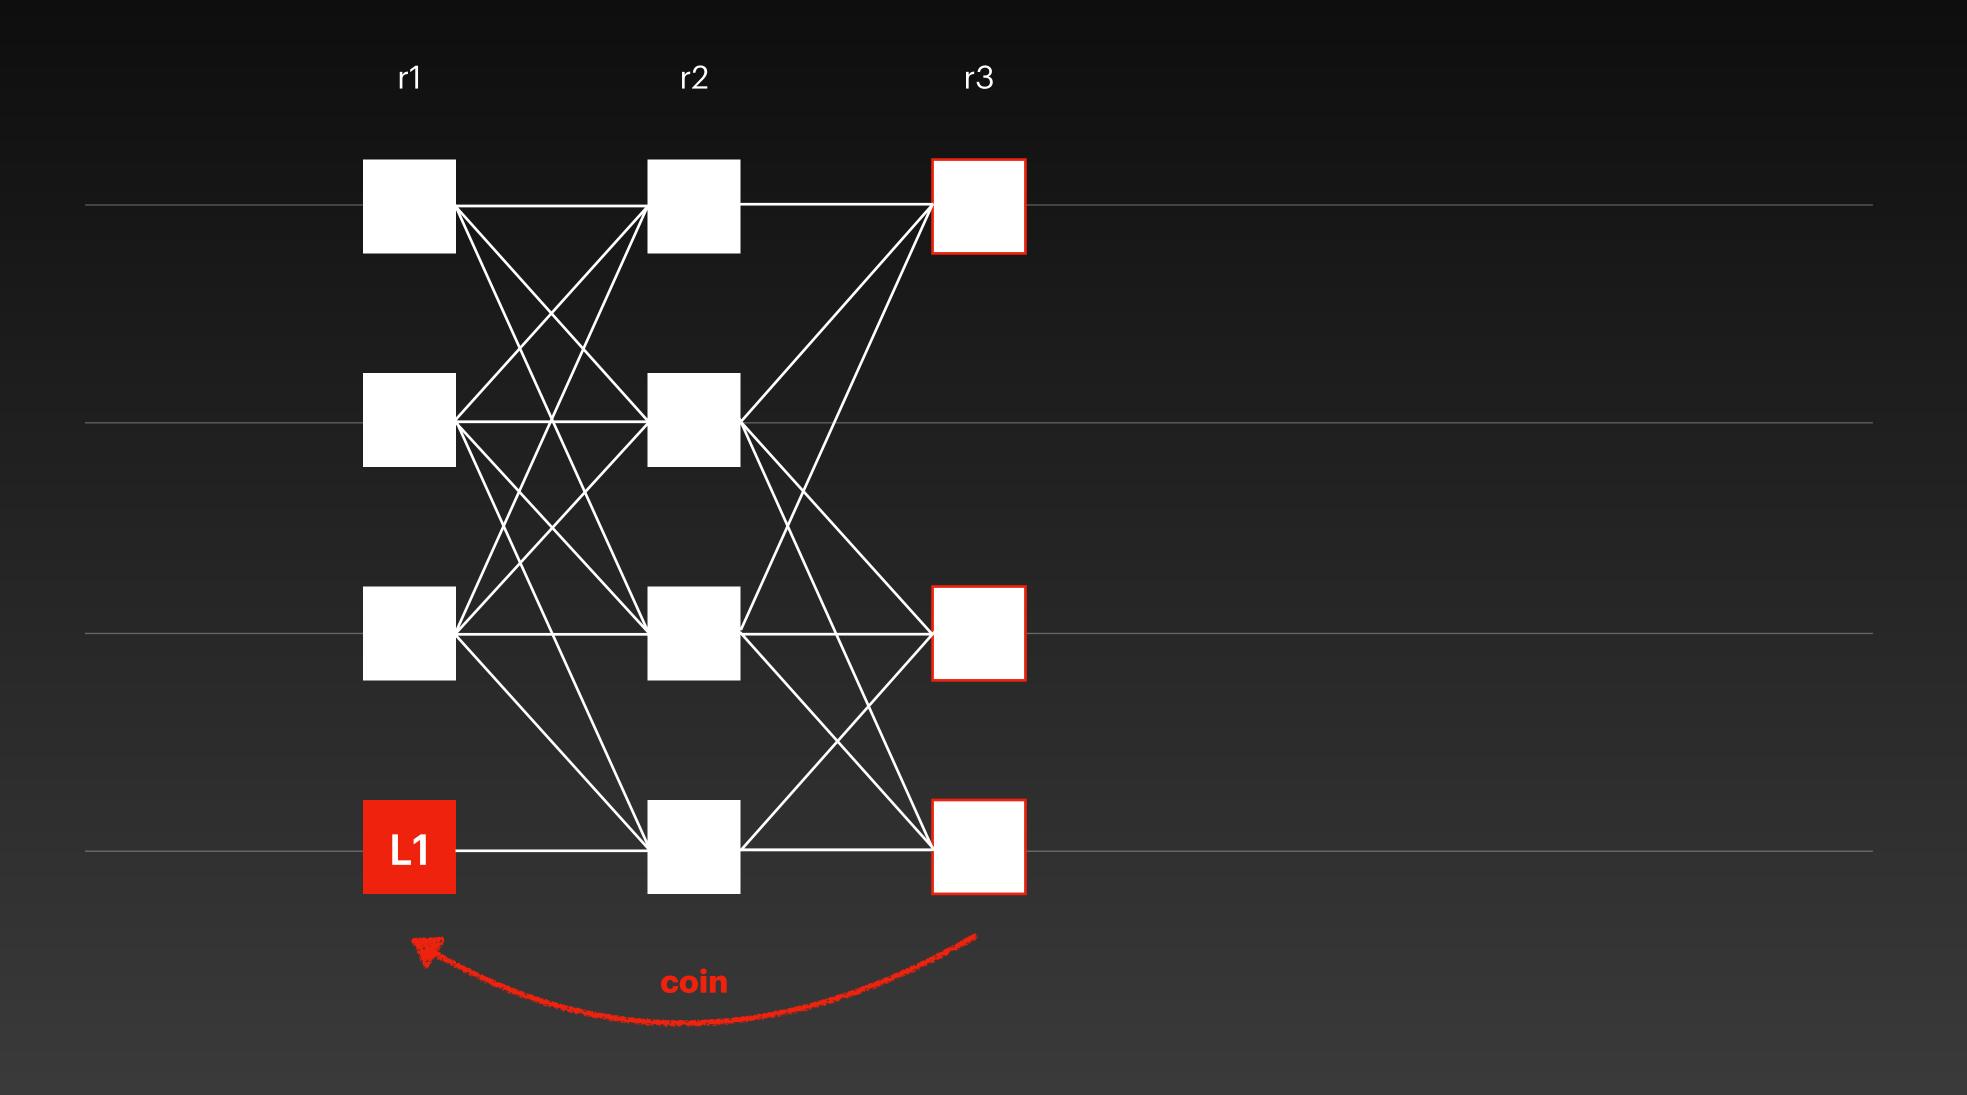

Zero-message asynchronous consensus

Tusk Add common coin & Interpret the DAG

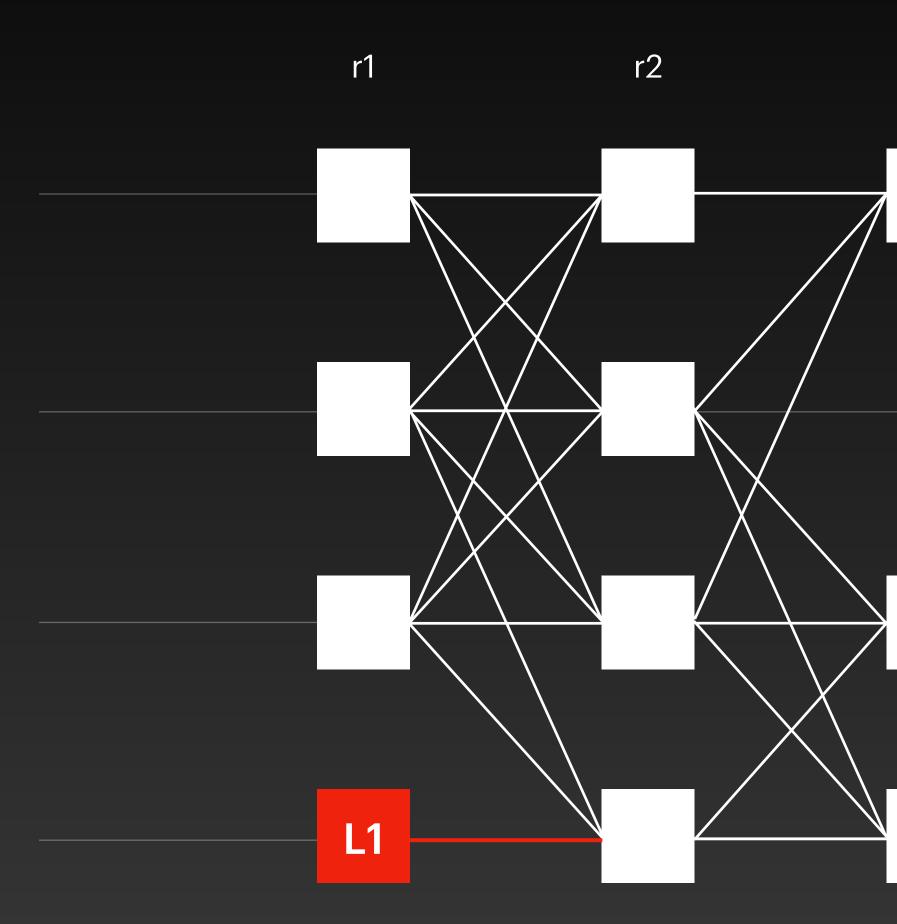

Tusk The random coin elects the leader of r-2

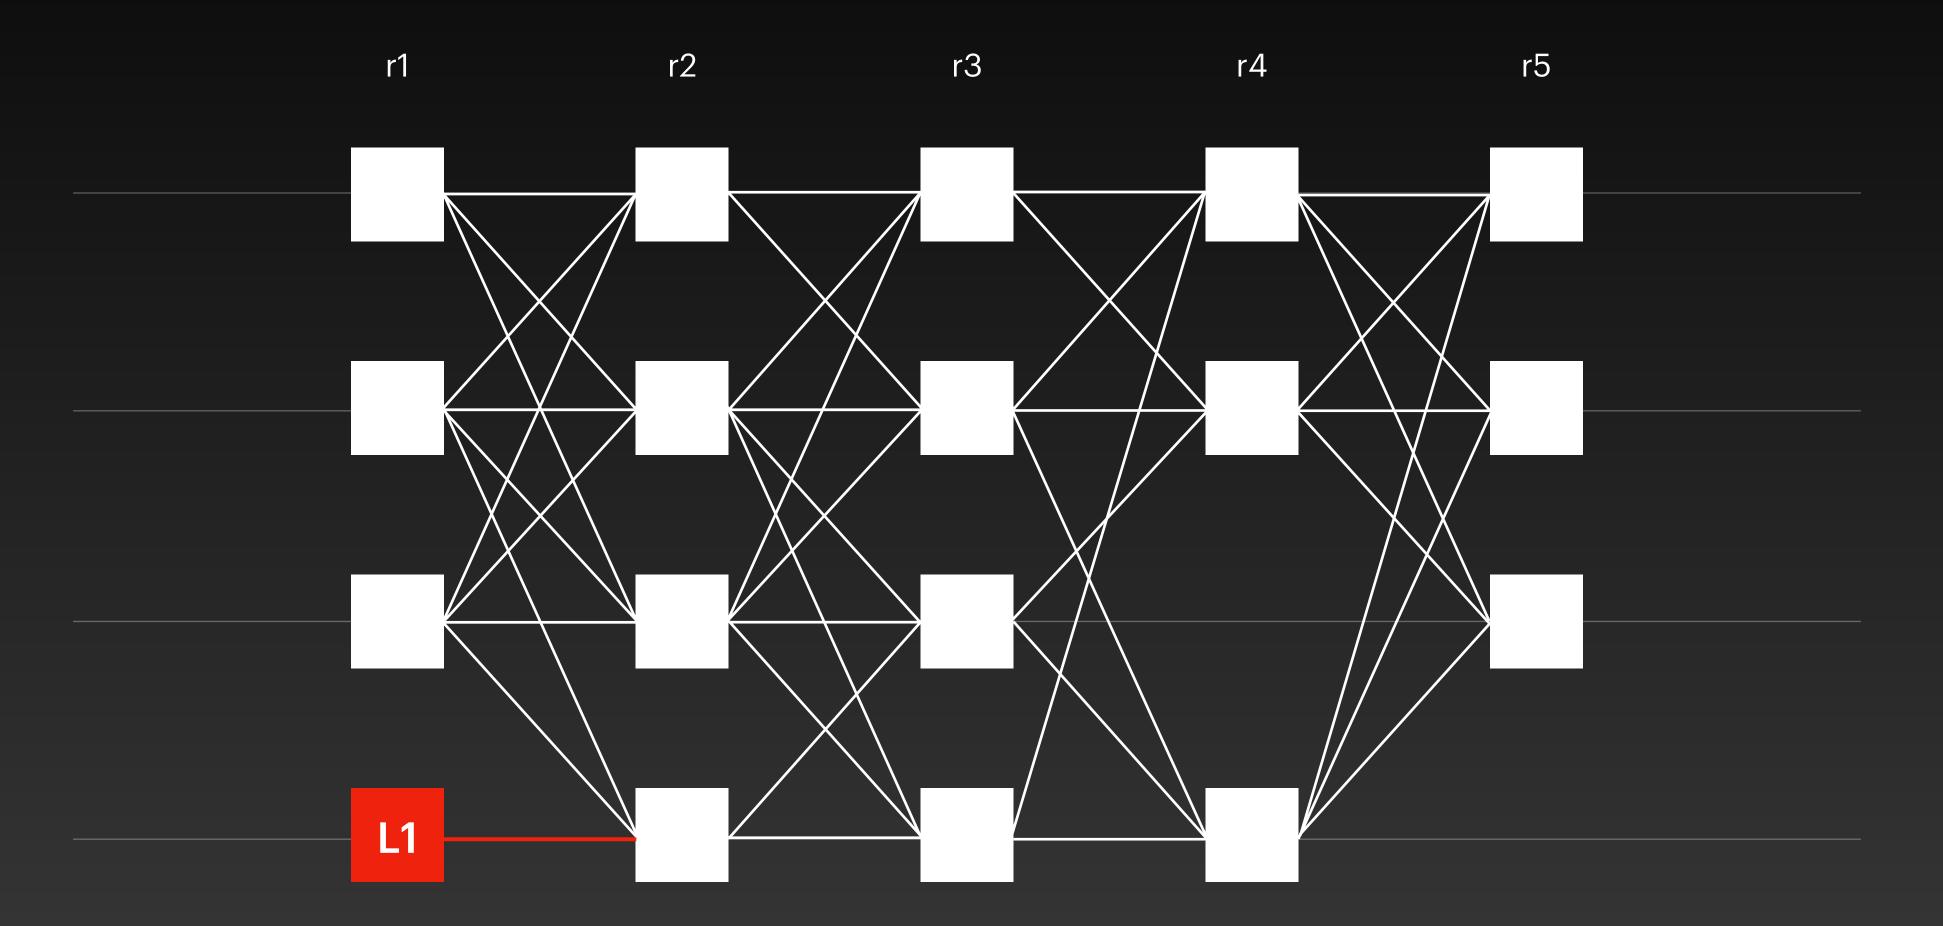

Tusk The leader needs f+1 links from round r-1

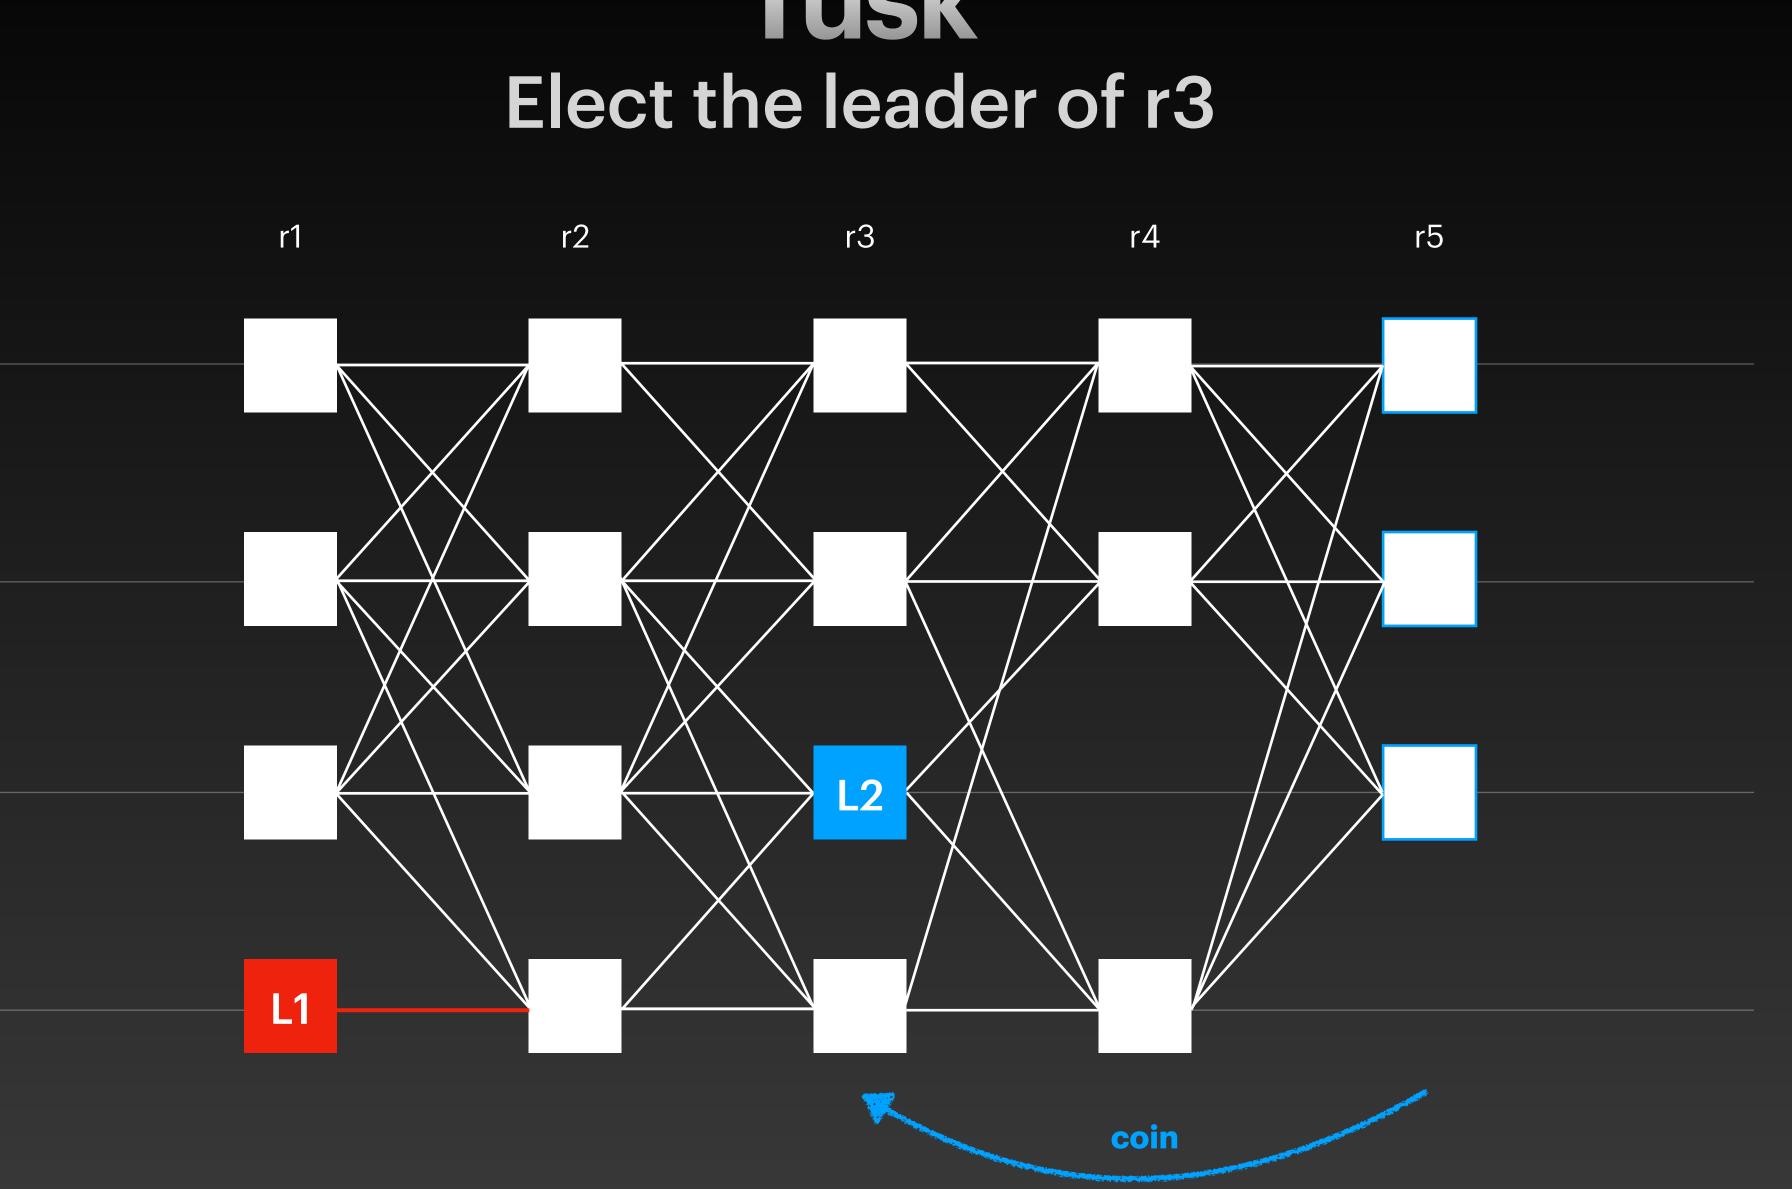

r3

Not enough support ! (Nothing is committed at this stage)

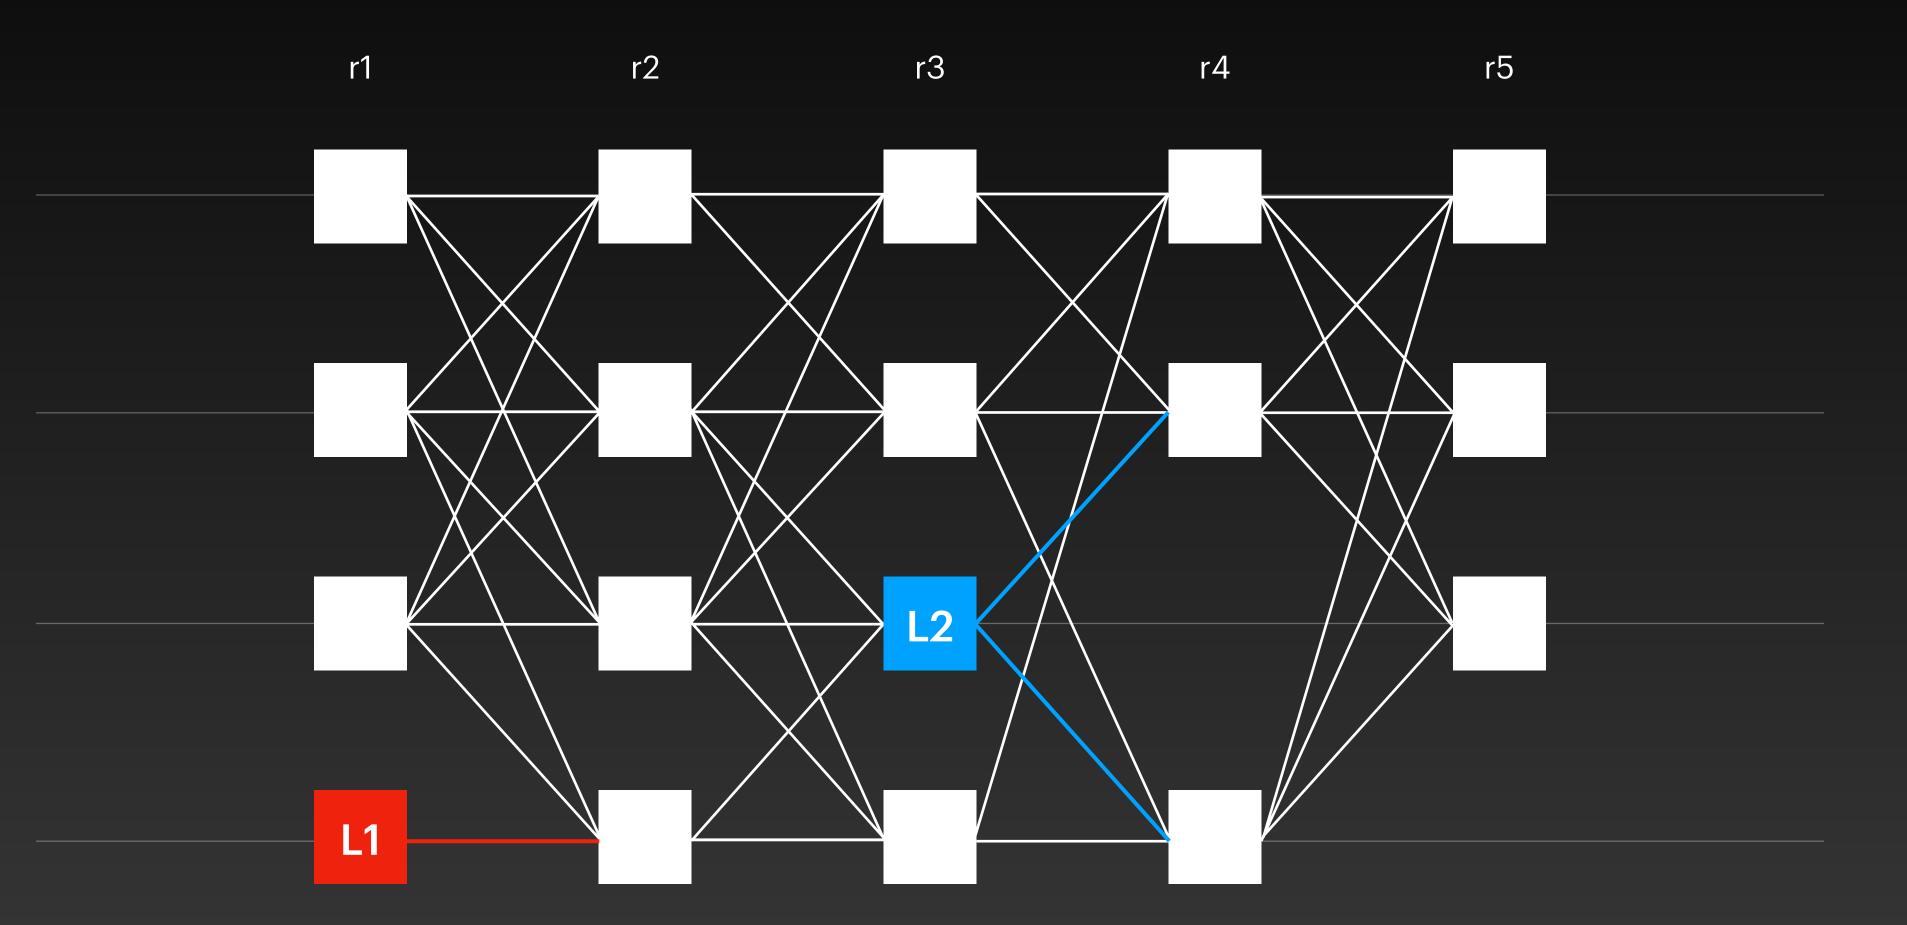

Tusk Nothing is committed and we keep build the DAG

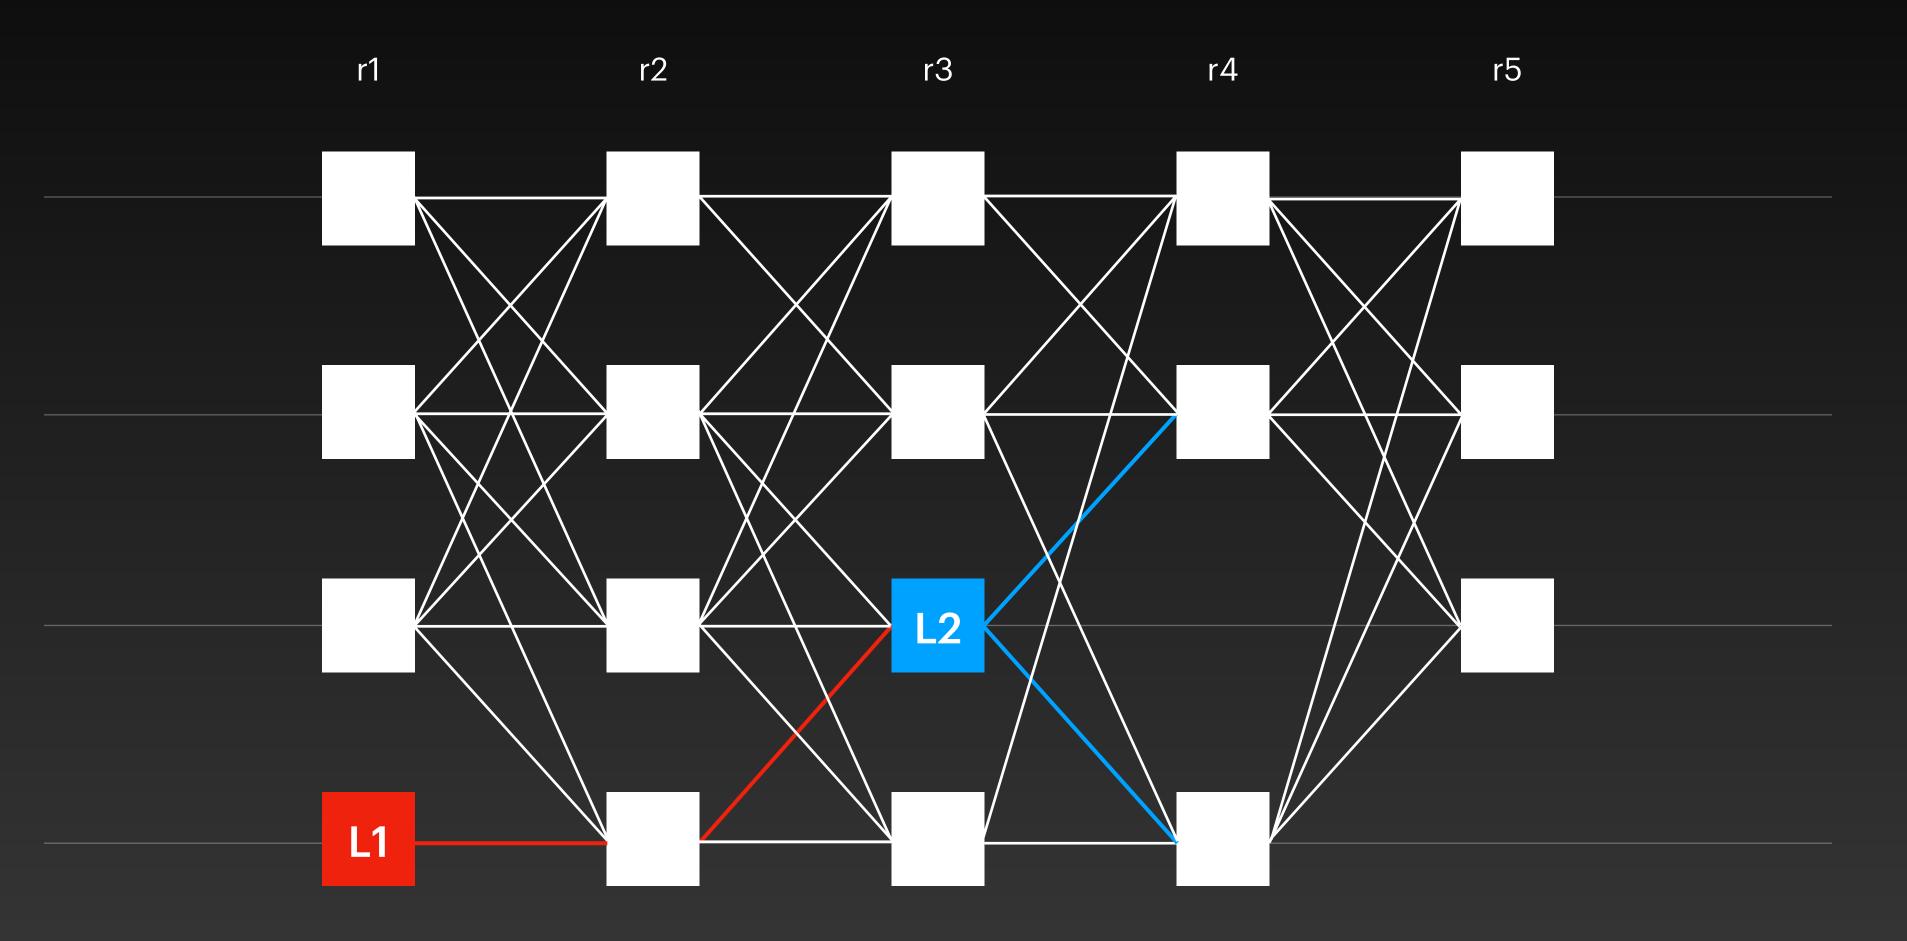

USK

Tusk Leader L2 has enough support

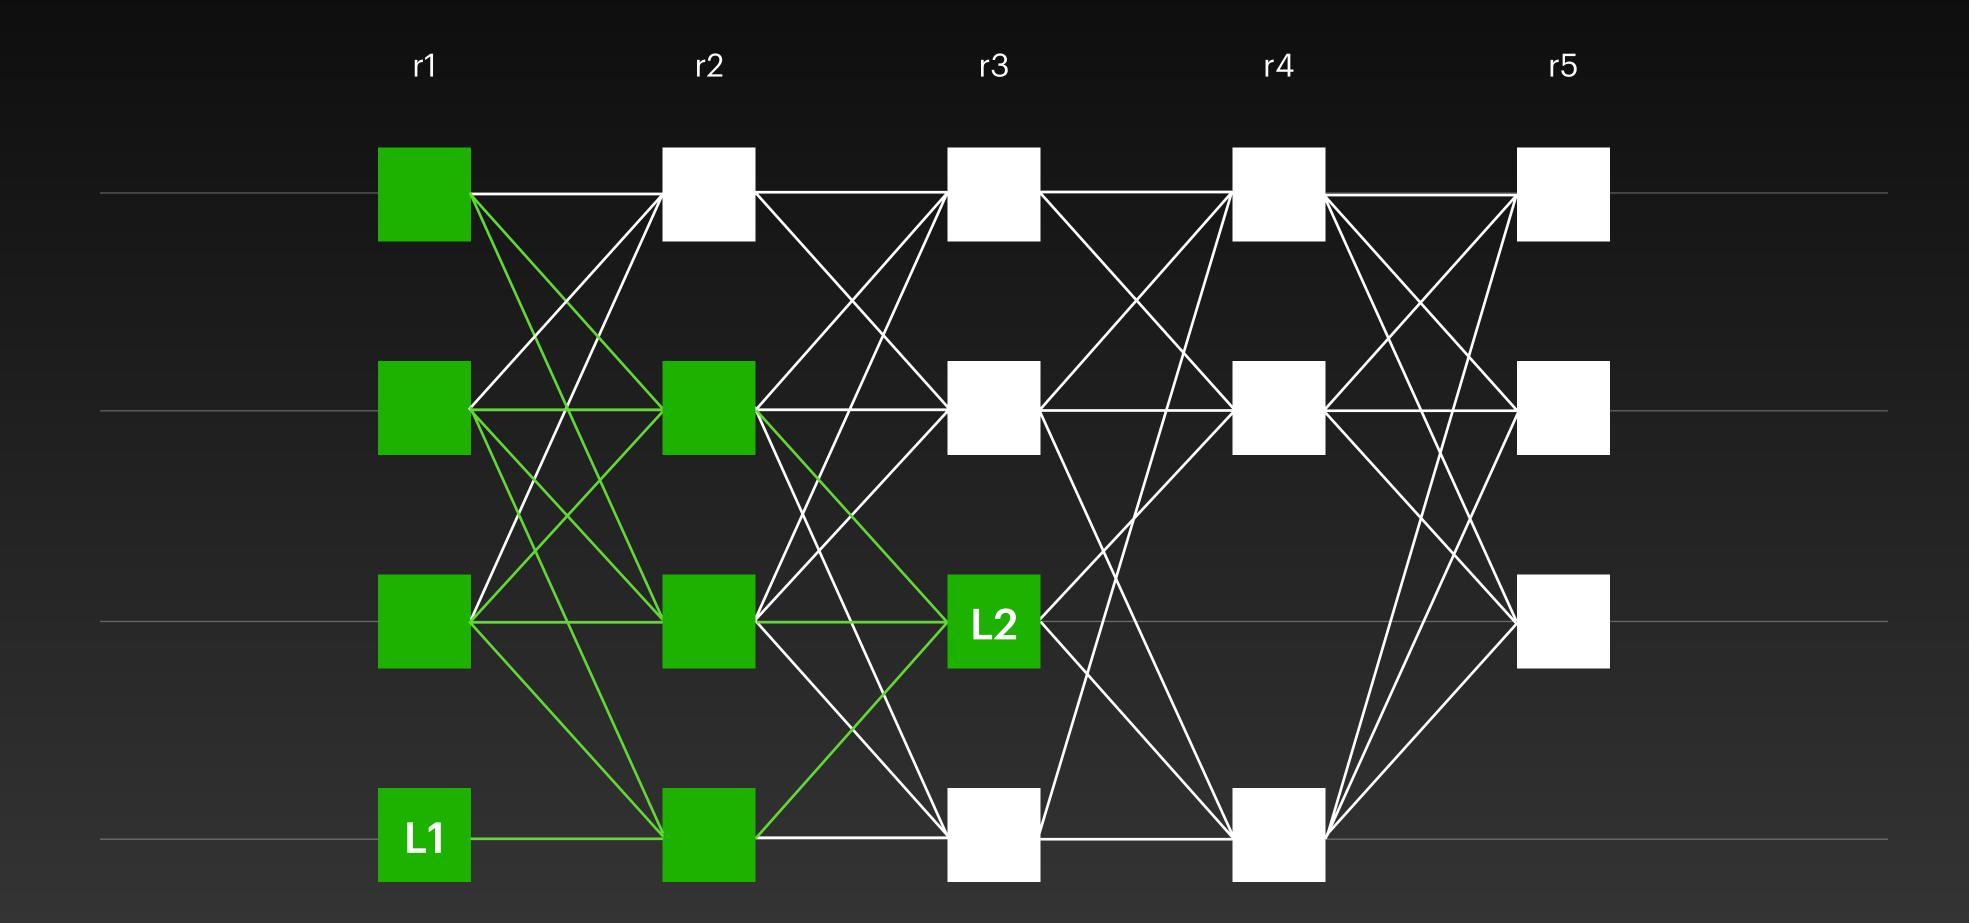

USK Leader L2 has links to leader L1

First commit L1

Then commit L2

Tusk Commit all the sub-DAG of the leader

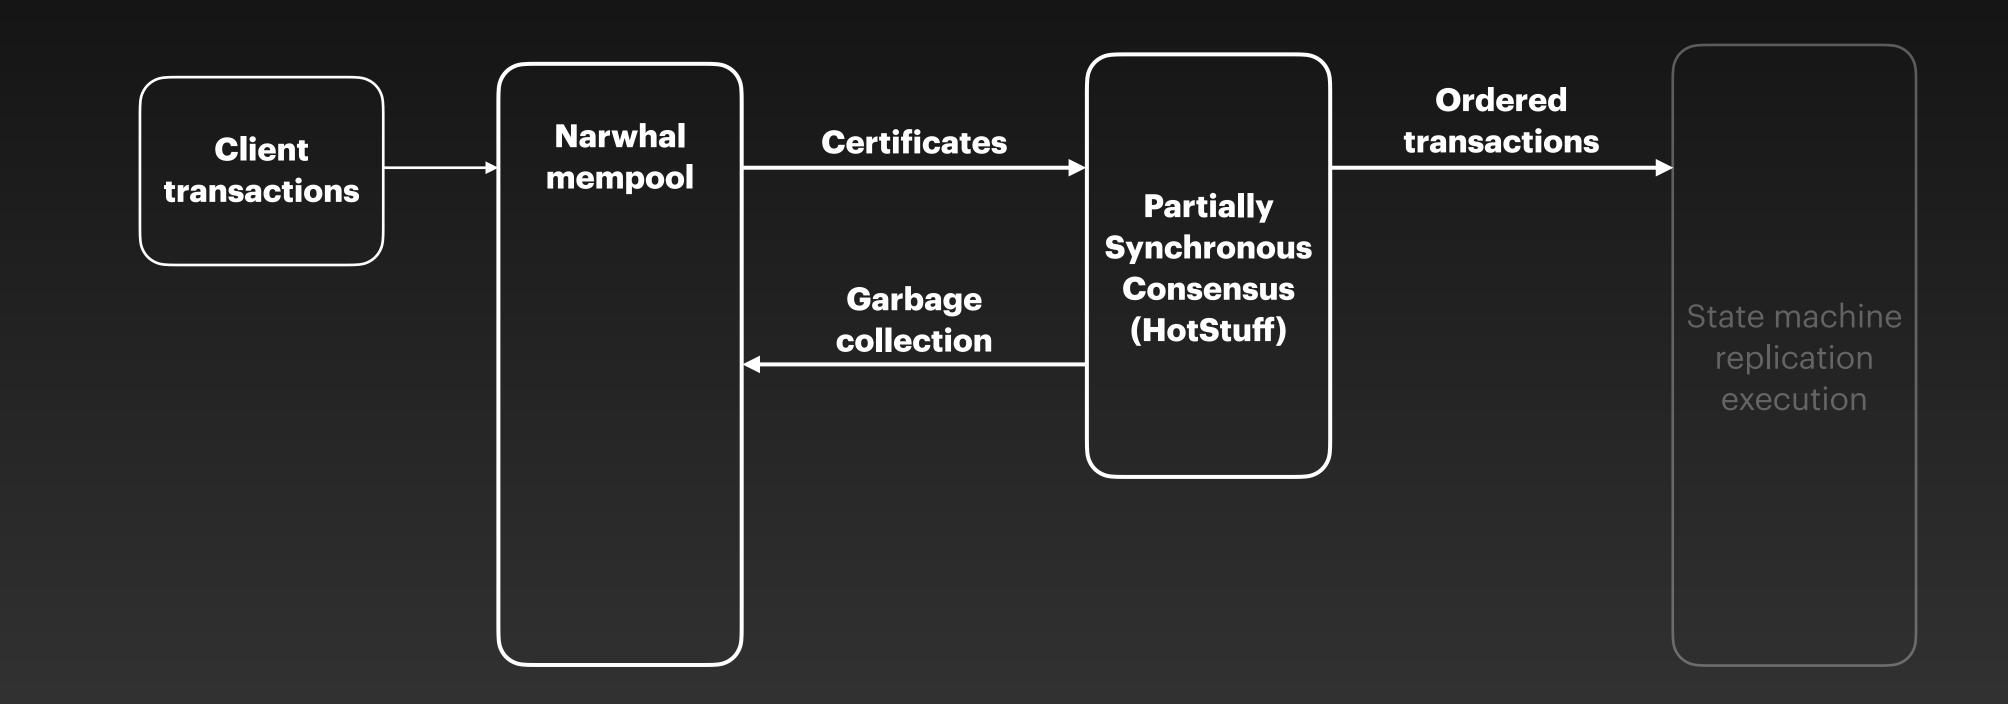

HotStuff on Steroids

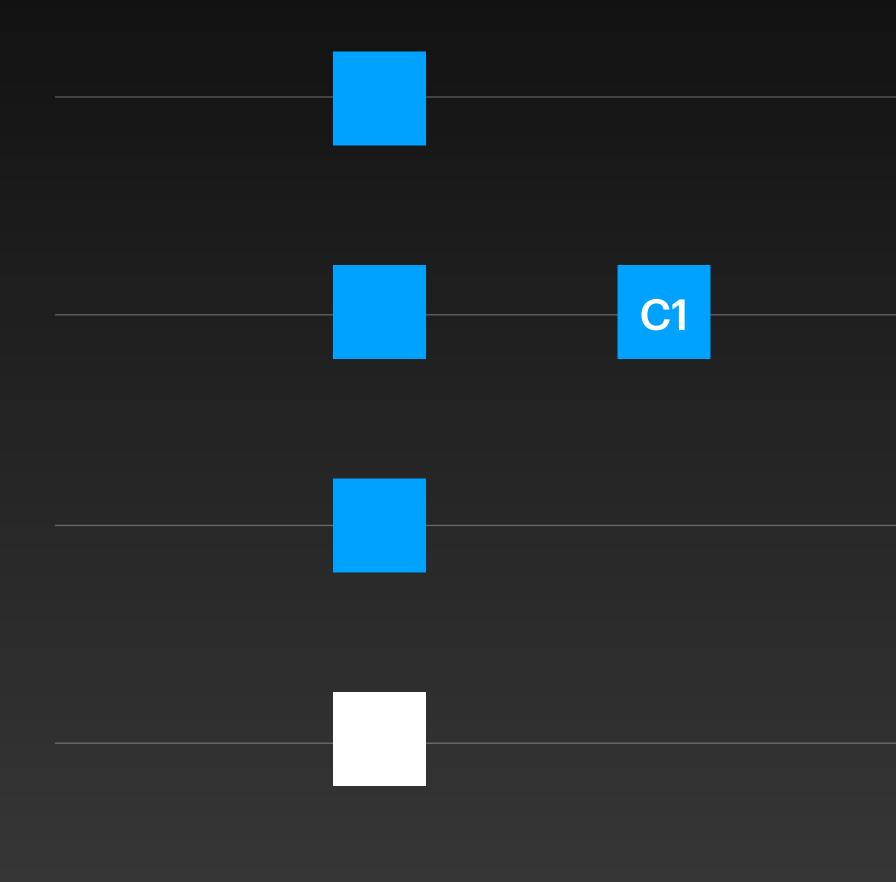

Just by replacing the mempool

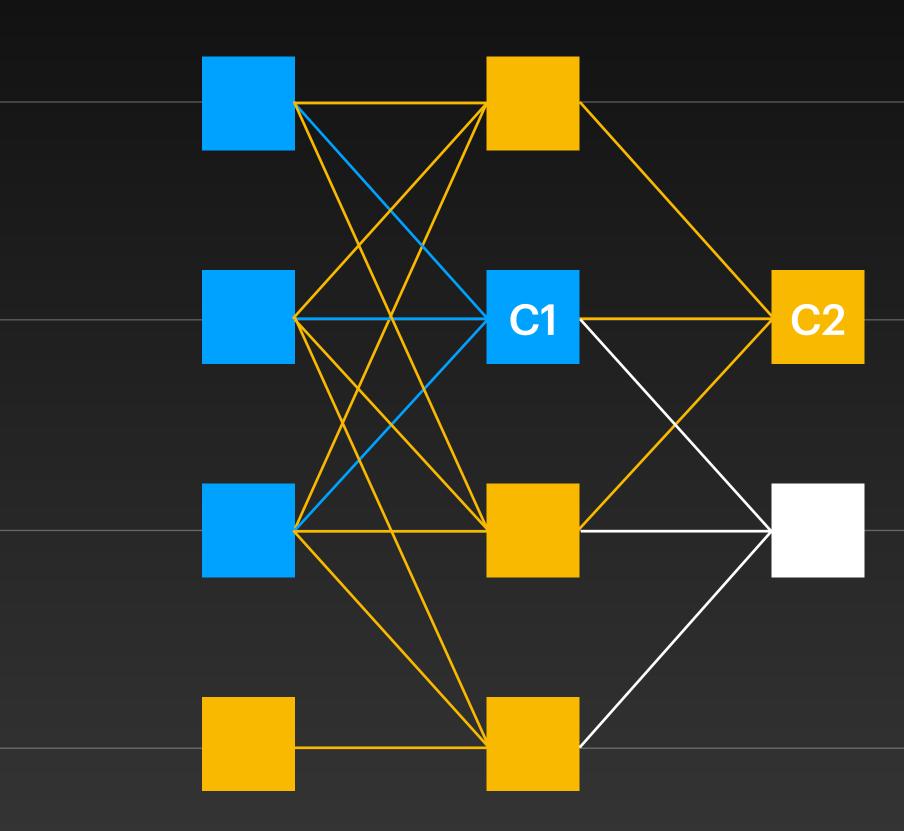

HotStuff on Narwhal Overview

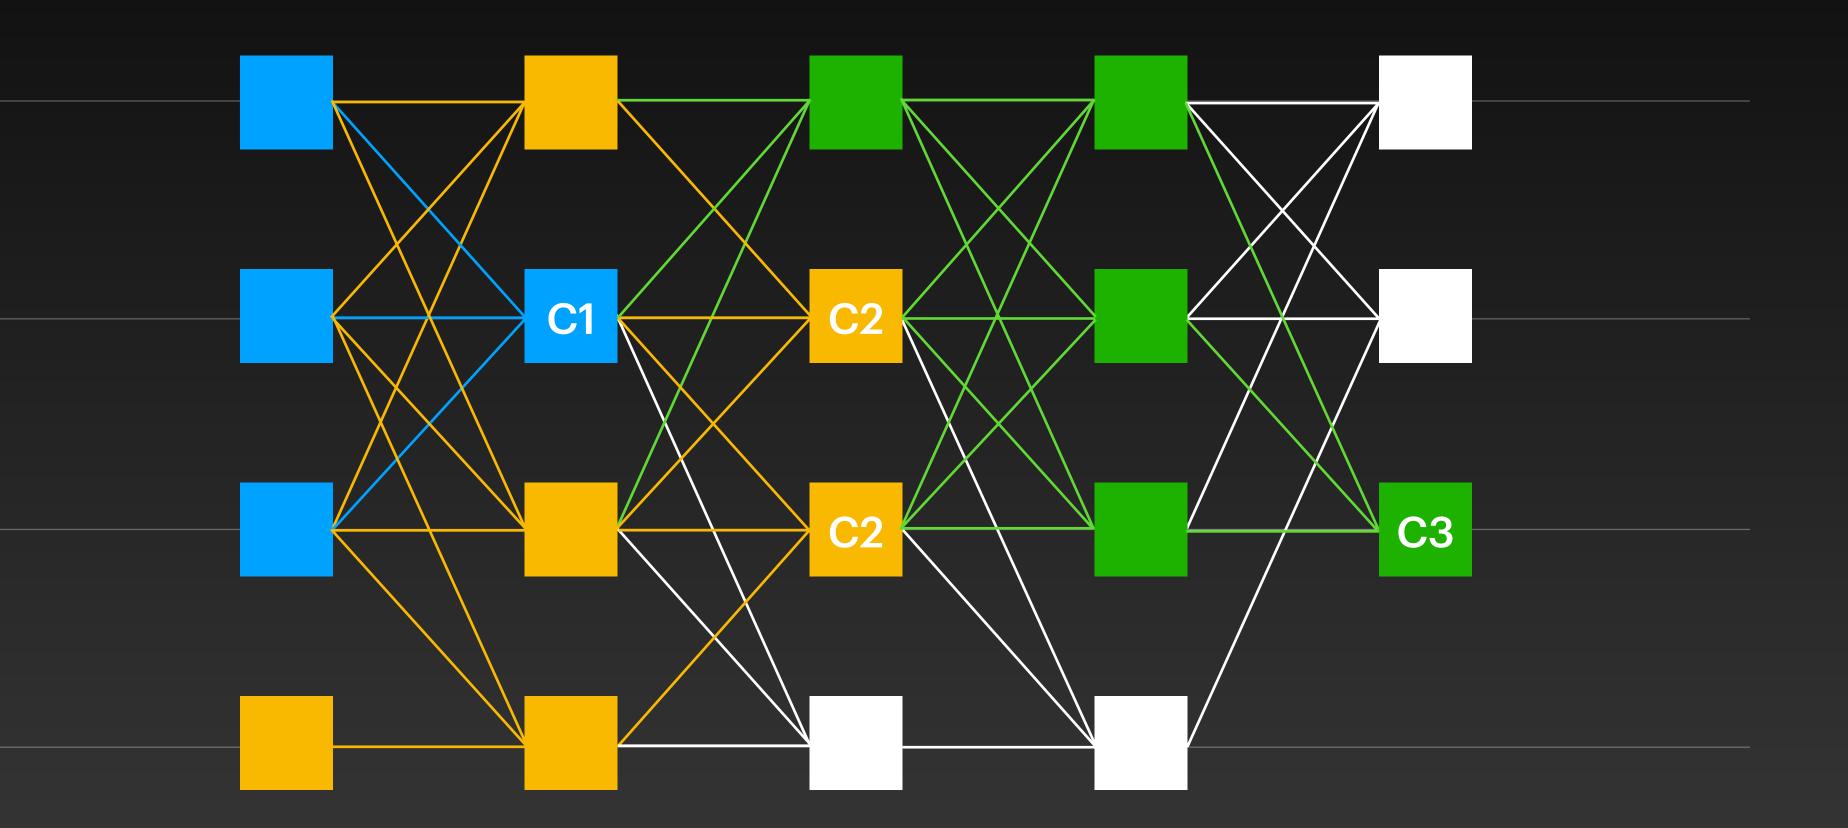

HotStuff on Narwhal Enhanced commit rule

HotStuff on Narwhal Enhanced commit rule

HotStuff on Narwhal Enhanced commit rule

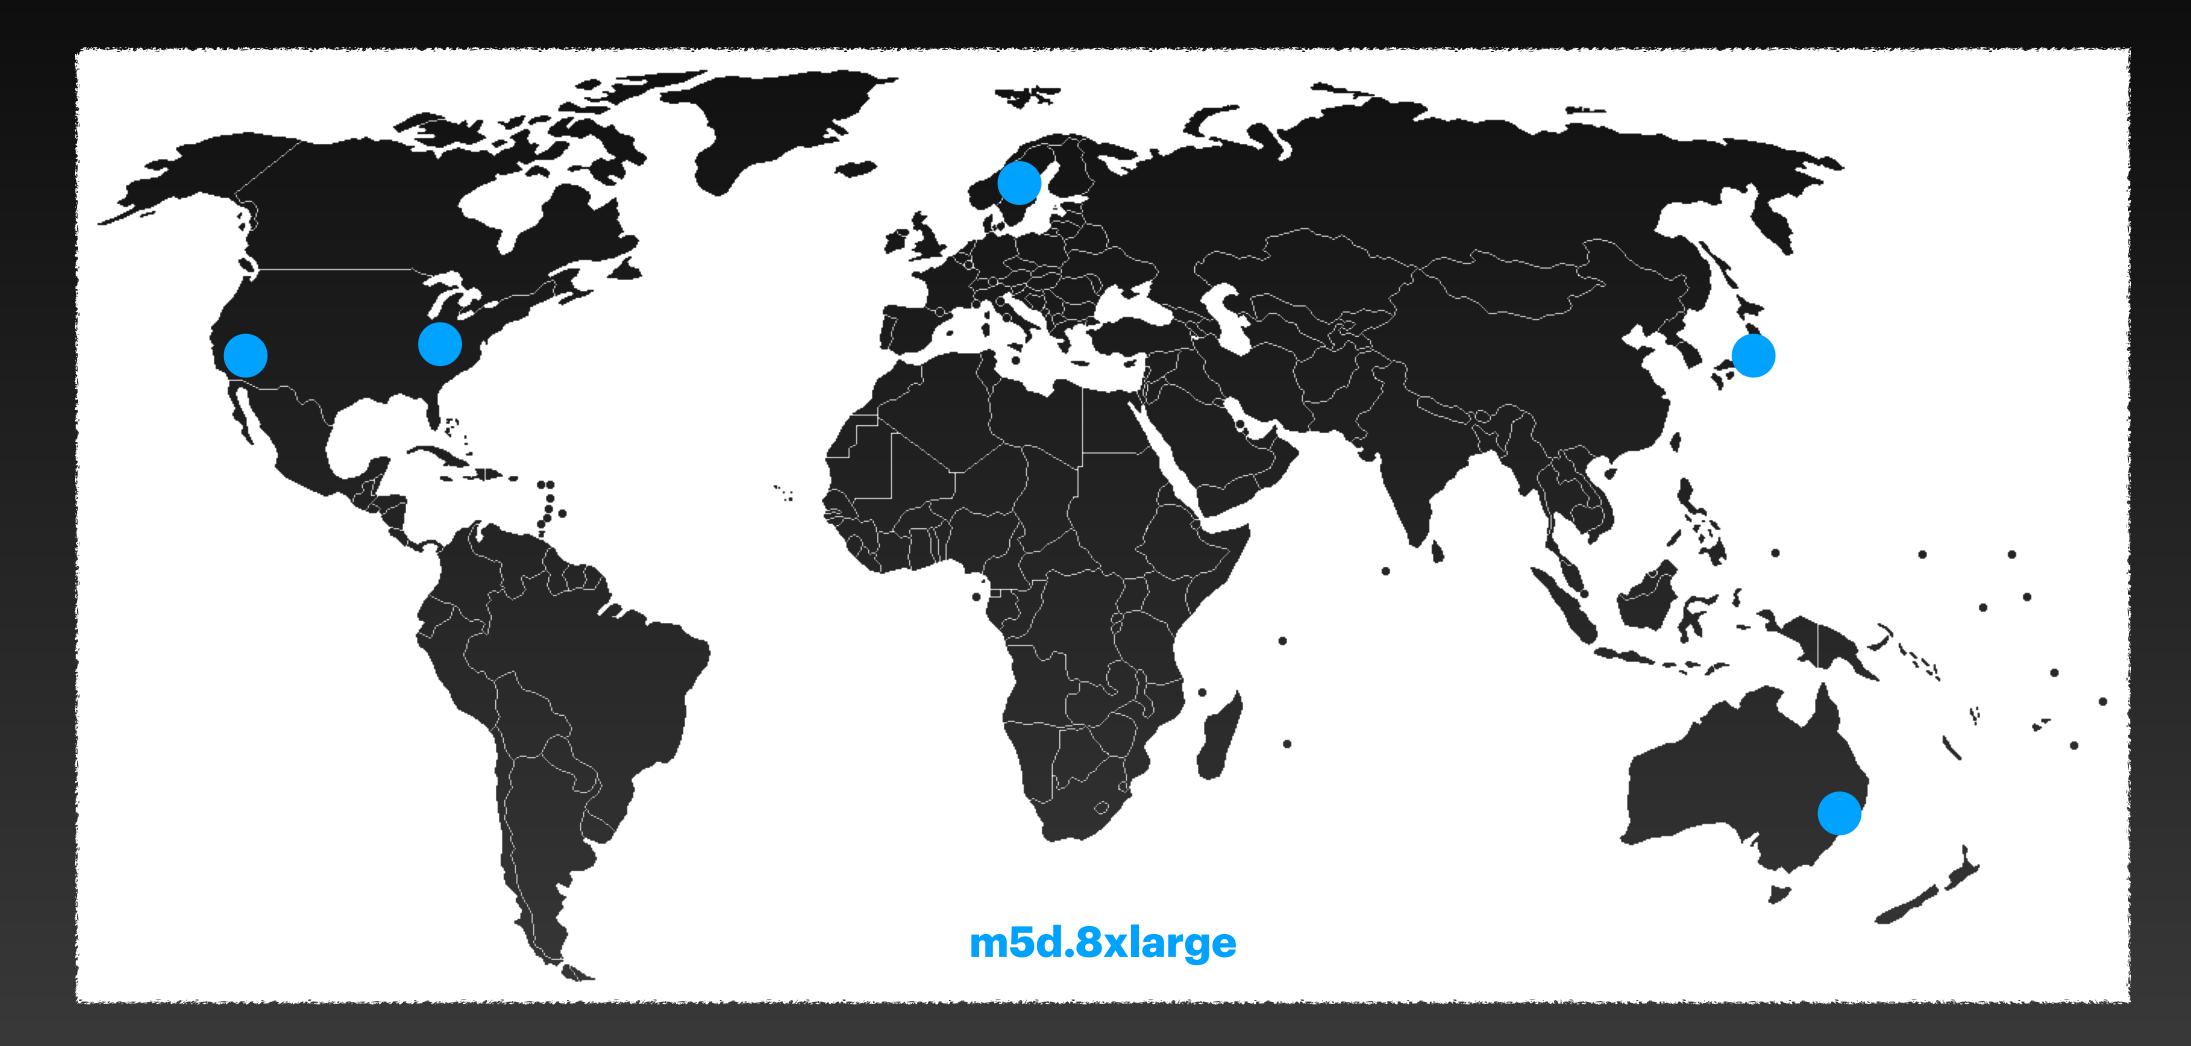

Implementation

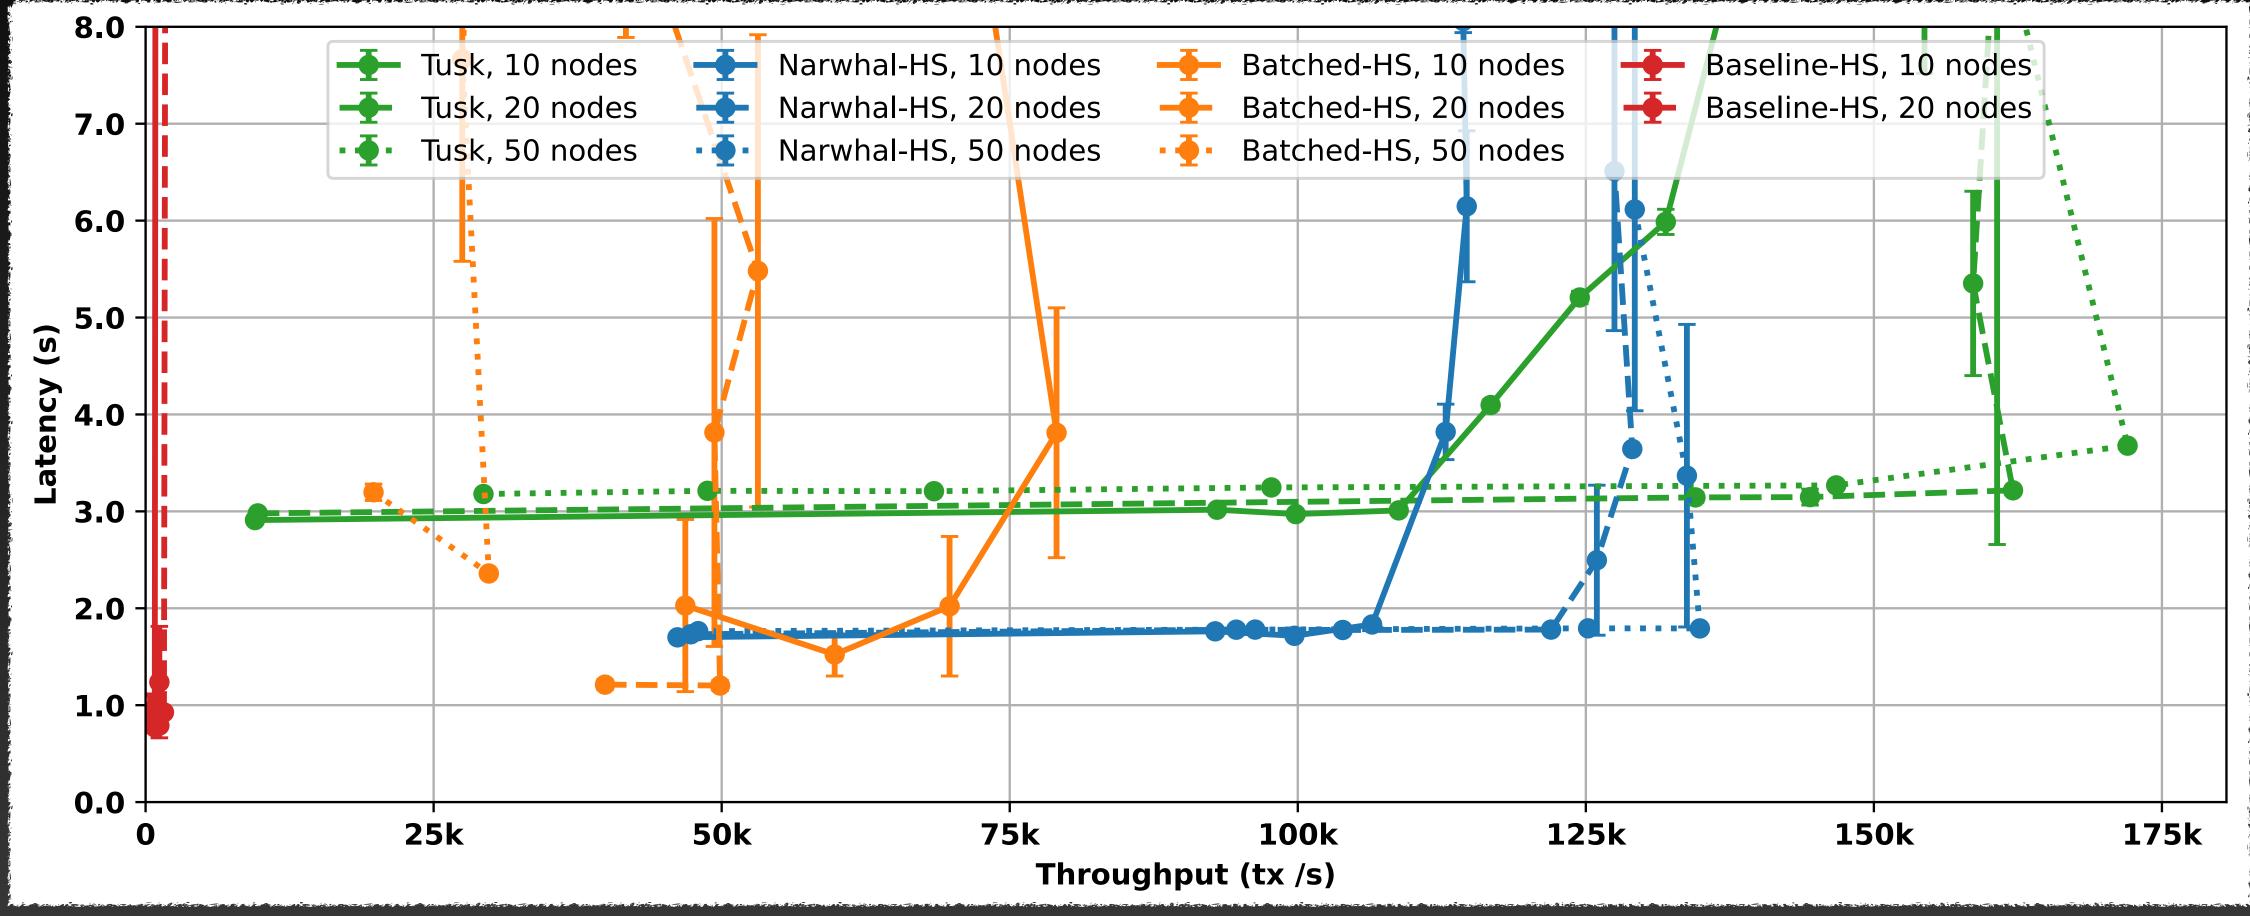

- Written in Rust
- Networking: Tokio (TCP)
- Storage: RocksDB
- Cryptography: ed25519-dalek

https://github.com/asonnino/narwhal

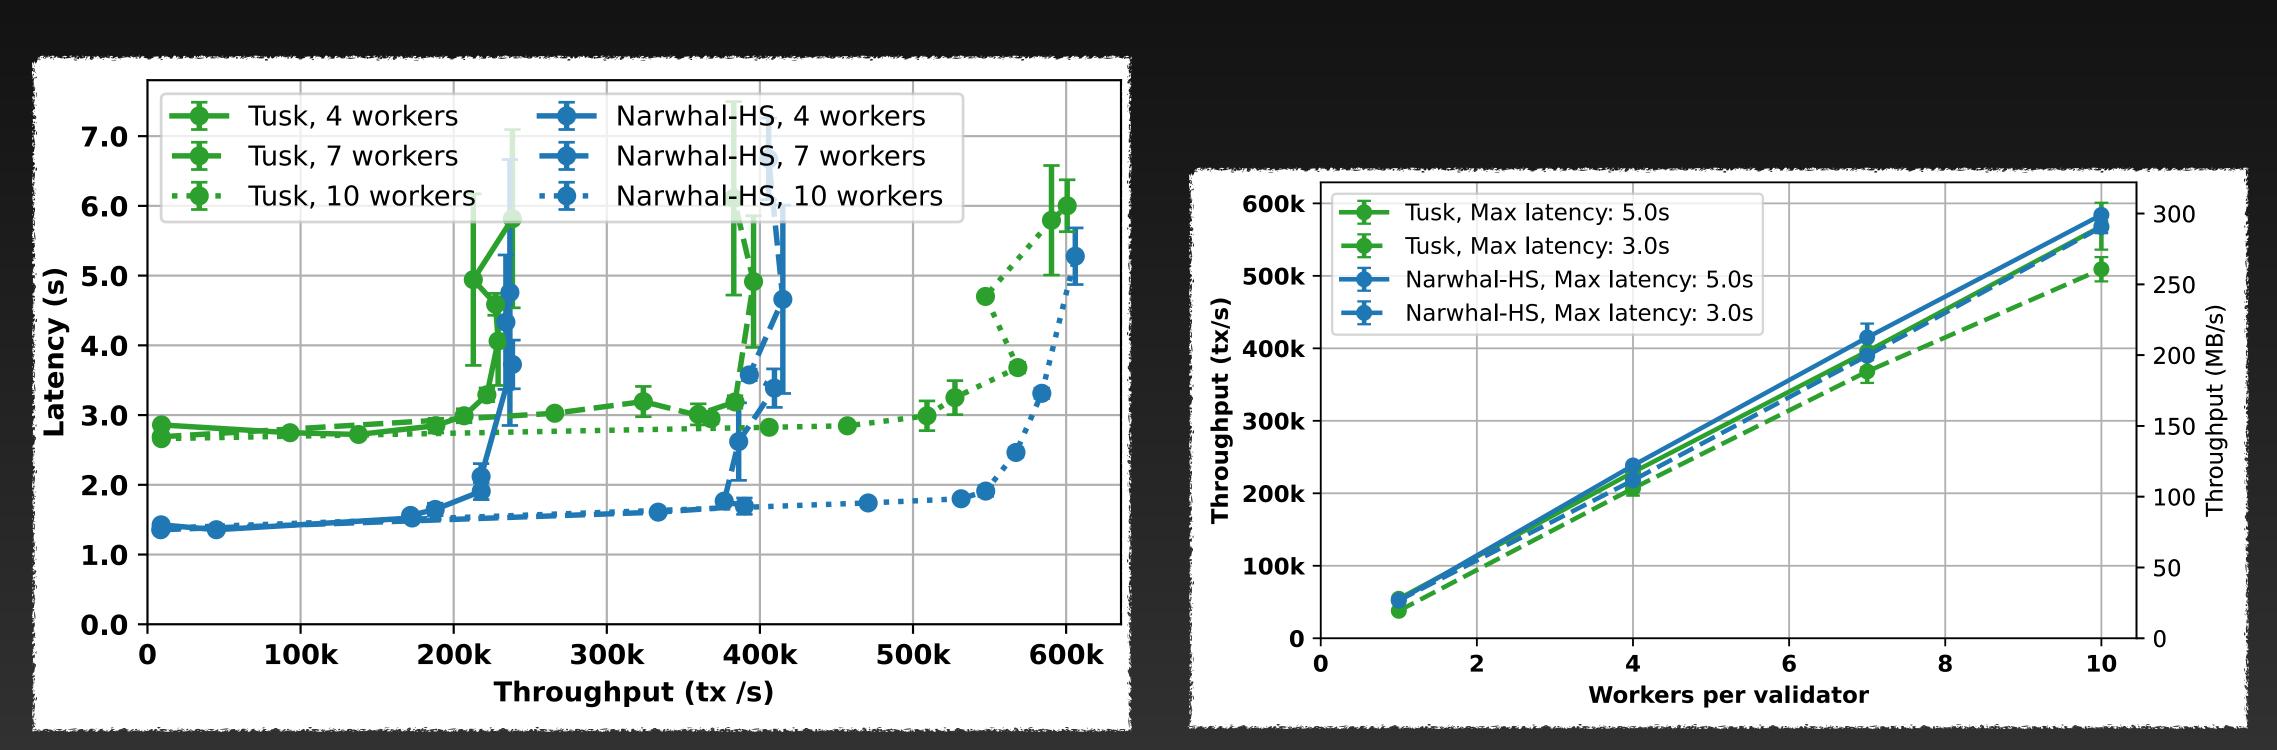

Evaluation Experimental setup on AWS

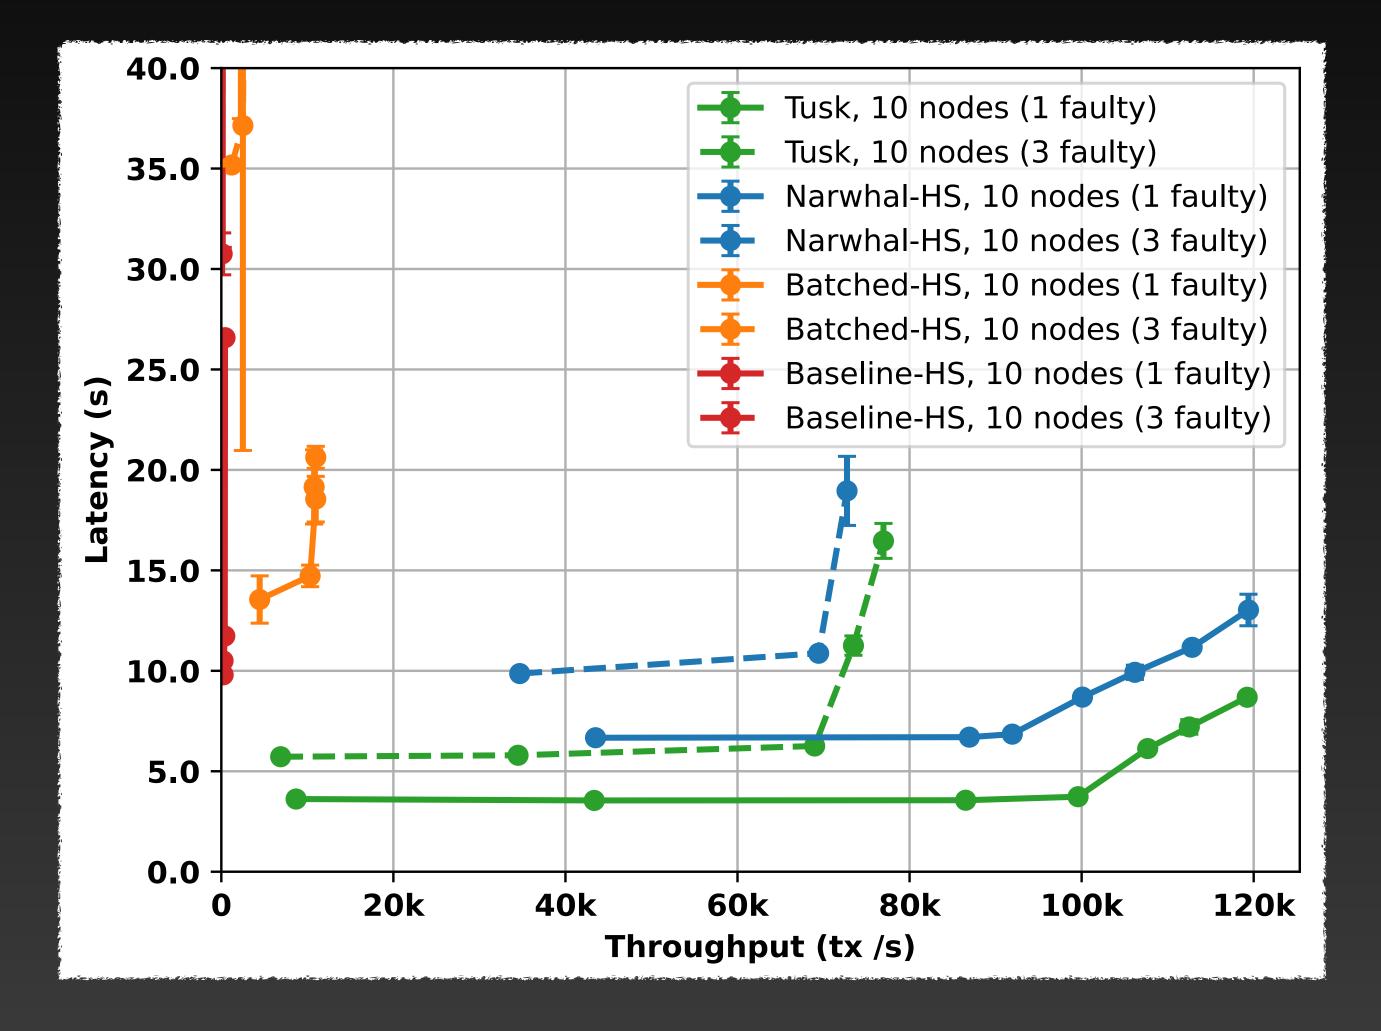

Evaluation Throughput latency graph

Evaluation Scalability

Evaluation Performance under faults

Conclusion

Narwhal & Tusk

- Scalable design, egalitarian resource utilizations

- Paper: https://arxiv.org/pdf/2105.11827.pdf
- Code: https://github.com/asonnino/narwhal

• Separate consensus and data dissemination for high performance
